About This Manual

The **ESP32 Technical Reference Manual** is addressed to application developers. The manual provides detailed and complete information on how to use the ESP32 memory and peripherals.

For pin definition, electrical characteristics and package information, please see the [ESP32 Datasheet](#).

1. System and Memory

1.1 Introduction

The ESP32 is a dual-core system with two Harvard Architecture Xtensa LX6 CPUs. All embedded memory, external memory and peripherals are located on the data bus and/or the instruction bus of these CPUs.

With some minor exceptions (see below), the address mapping of two CPUs is symmetric, meaning that they use the same addresses to access the same memory. Multiple peripherals in the system can access embedded memory via DMA.

The two CPUs are named “PRO_CPU” and “APP_CPU” (for “protocol” and “application”), however, for most purposes the two CPUs are interchangeable.

1.2 Features

- Address Space
 - Symmetric address mapping
 - 4 GB (32-bit) address space for both data bus and instruction bus
 - 1296 KB embedded memory address space
 - 19704 KB external memory address space
 - 512 KB peripheral address space
 - Some embedded and external memory regions can be accessed by either data bus or instruction bus
 - 328 KB DMA address space
- Embedded Memory
 - 448 KB Internal ROM
 - 520 KB Internal SRAM
 - 8 KB RTC FAST Memory
 - 8 KB RTC SLOW Memory
- External Memory

Off-chip SPI memory can be mapped into the available address space as external memory. Parts of the embedded memory can be used as transparent cache for this external memory.

 - Supports up to 16 MB off-Chip SPI Flash.
 - Supports up to 8 MB off-Chip SPI SRAM.
- Peripherals
 - 41 peripherals
- DMA
 - 13 modules are capable of DMA operation

The block diagram in Figure 1 illustrates the system structure, and the block diagram in Figure 2 illustrates the address map structure.

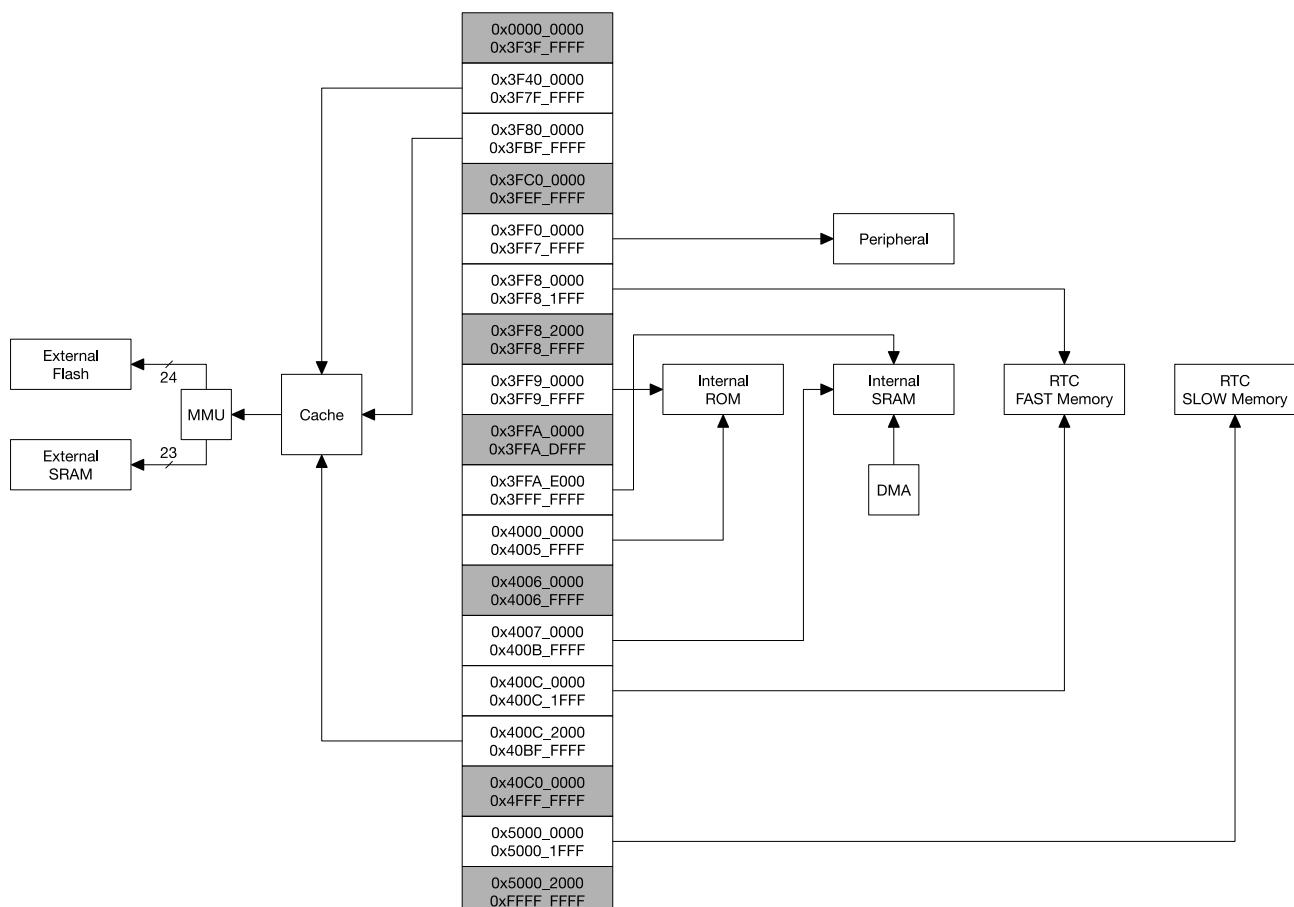

Figure 2: System Address Mapping

1.3 Functional Description

1.3.1 Address Mapping

Each of the two Harvard Architecture Xtensa LX6 CPUs has 4 GB (32-bit) address space. Address spaces are symmetric between the two CPUs.

Addresses below 0x4000_0000 are serviced using the data bus. Addresses in the range 0x4000_0000 ~ 0x4FFF_FFFF are serviced using the instruction bus. Finally, addresses over and including 0x5000_0000 are shared by the data and instruction bus.

The data bus and instruction bus are both little-endian: for example, byte addresses 0x0, 0x1, 0x2, 0x3 access the least significant, second least significant, second most significant, and the most significant bytes of the 32-bit word stored at the 0x0 address, respectively. The CPU can access data bus addresses via aligned or non-aligned byte, half-word and word read-and-write operations. The CPU can read and write data through the instruction bus, but only in a **word aligned manner**; non-word-aligned access will cause a CPU exception.

Each CPU can directly access embedded memory through both the data bus and the instruction bus, external memory which is mapped into the address space (via transparent caching & MMU), and peripherals. Table 1 illustrates address ranges that can be accessed by each CPU's data bus and instruction bus.

Some embedded memories and some external memories can be accessed via the data bus or the instruction bus. In these cases, the same memory is available to either of the CPUs at two address ranges.

Table 1: Address Mapping

	0x5000_2000	0xFFFF_FFFF		Reserved

1.3.2 Embedded Memory

The Embedded Memory consists of four segments: internal ROM (448 KB), internal SRAM (520 KB), RTC FAST memory (8 KB) and RTC SLOW memory (8 KB).

The 448 KB internal ROM is divided into two parts: Internal ROM 0 (384 KB) and Internal ROM 1 (64 KB).

The 520 KB internal SRAM is divided into three parts: Internal SRAM 0 (192 KB), Internal SRAM 1 (128 KB), and Internal SRAM 2 (200 KB).

RTC FAST Memory and RTC SLOW Memory are both implemented as SRAM.

Table 2 lists all embedded memories and their address ranges on the data and instruction buses.

Table 2: Embedded Memory Address Mapping

1.3.2.1 Internal ROM 0

The capacity of Internal ROM 0 is 384 KB. It is accessible by both CPUs through the address range 0x4000_0000 ~ 0x4005_FFFF, which is on the instruction bus.

The address range of the first 32 KB of the ROM 0 (0x4000_0000 ~ 0x4000_7FFF) can be remapped in order to access a part of Internal SRAM 1 that normally resides in a memory range of 0x400B_0000 ~ 0x400B_7FFF. While remapping, the 32 KB SRAM cannot be accessed by an address range of 0x400B_0000 ~ 0x400B_7FFF any more, but it can still be accessible through the data bus (0x3FFE_8000 ~ 0x3FFE_FFFF). This can be done on a per-CPU basis: setting bit 0 of register DPORTE_PRO_BOOT_REMAP_CTRL_REG or DPORTE_APP_BOOT_REMAP_CTRL_REG will remap SRAM for the PRO_CPU and APP_CPU, respectively.

1.3.2.2 Internal ROM 1

The capacity of Internal ROM 1 is 64 KB. It can be read by either CPU at an address range 0x3FF9_0000 ~ 0x3FF9_FFFF of the data bus.

1.3.2.3 Internal SRAM 0

The capacity of Internal SRAM 0 is 192 KB. Hardware can be configured to use the first 64KB to cache external memory access. When not used as cache, the first 64KB can be read and written by either CPU at addresses 0x4007_0000 ~ 0x4007_7FFF of the instruction bus. The remaining 128 KB can always be read and written by either CPU at addresses 0x4007_8000 ~ 0x4007_FFFF of instruction bus.

1.3.2.4 Internal SRAM 1

The capacity of Internal SRAM 1 is 128 KB. Either CPU can read and write this memory at addresses 0x3FFE_0000 ~ 0x3FFF_FFFF of the data bus, and also at addresses 0x400A_0000 ~ 0x400B_FFFF of the instruction bus.

The address range accessed via the instruction bus is in reverse order (word-wise) compared to access via the data bus. That is to say, address

0x3FFE_0000 and 0x400B_FFFC access the same word

0x3FFE_0004 and 0x400B_FFF8 access the same word

0x3FFE_0008 and 0x400B_FFF4 access the same word

.....

0x3FFF_FFF4 and 0x400A_0008 access the same word

0x3FFF_FFF8 and 0x400A_0004 access the same word

0x3FFF_FFFC and 0x400A_0000 access the same word

The data bus and instruction bus of the CPU are still both little-endian, so the byte order of individual words is not reversed between address spaces. For example, address

0x3FFE_0000 accesses the least significant byte in the word accessed by 0x400B_FFFC.

0x3FFE_0001 accesses the second least significant byte in the word accessed by 0x400B_FFFC.

0x3FFE_0002 accesses the second most significant byte in the word accessed by 0x400B_FFFC.

0x3FFE_0003 accesses the most significant byte in the word accessed by 0x400B_FFFC.

0x3FFE_0004 accesses the least significant byte in the word accessed by 0x400B_FFF8.

0x3FFE_0005 accesses the second least significant byte in the word accessed by 0x400B_FFF8.

0x3FFE_0006 accesses the second most significant byte in the word accessed by 0x400B_FFF8.

0x3FFE_0007 accesses the most significant byte in the word accessed by 0x400B_FFF8.

.....

0x3FFF_FFF8 accesses the least significant byte in the word accessed by 0x400A_0004.

0x3FFF_FFF9 accesses the second least significant byte in the word accessed by 0x400A_0004.

0x3FFF_FFFA accesses the second most significant byte in the word accessed by 0x400A_0004.

0x3FFF_FFFB accesses the most significant byte in the word accessed by 0x400A_0004.

0x3FFF_FFFC accesses the least significant byte in the word accessed by 0x400A_0000.

0x3FFF_FFFD accesses the second most significant byte in the word accessed by 0x400A_0000.

0x3FFF_FFFE accesses the second most significant byte in the word accessed by 0x400A_0000.

0x3FFF_FFFF accesses the most significant byte in the word accessed by 0x400A_0000.

Part of this memory can be remapped onto the ROM 0 address space. See [Internal Rom 0](#) for more information.

1.3.2.5 Internal SRAM 2

The capacity of Internal SRAM 2 is 200 KB. It can be read and written by either CPU at addresses 0x3FFA_E000 ~ 0x3FFD_FFFF on the data bus.

1.3.2.6 DMA

DMA uses the same addressing as the CPU data bus to read and write Internal SRAM 1 and Internal SRAM 2. This means DMA uses an address range of 0x3FFE_0000 ~ 0x3FFF_FFFF to read and write Internal SRAM 1 and an address range of 0x3FFA_E000 ~ 0x3FFD_FFFF to read and write Internal SRAM 2.

In the ESP32, 13 peripherals are equipped with DMA. Table 3 lists these peripherals.

Table 3: Module with DMA

UART0	UART1	UART2
SPI1	SPI2	SPI3
I2S0	I2S1	
SDIO Slave	SDMMC

BT	WIFI	

1.3.2.7 RTC FAST Memory

RTC FAST Memory is 8 KB of SRAM. It can be read and written by PRO_CPU only at an address range of 0x3FF8_0000 ~ 0x3FF8_1FFF on the data bus or at an address range of 0x400C_0000 ~ 0x400C_1FFF on the instruction bus. Unlike most other memory regions, RTC FAST memory cannot be accessed by the APP_CPU.

The two address ranges of PRO_CPU access RTC FAST Memory in the same order, so, for example, addresses 0x3FF8_0000 and 0x400C_0000 access the same word. **On the APP_CPU, these address ranges do not provide access to RTC FAST Memory or any other memory location.**

1.3.2.8 RTC SLOW Memory

RTC SLOW Memory is 8 KB of SRAM which can be read and written by either CPU at an address range of 0x5000_0000 ~ 0x5000_1FFF. This address range is shared by both the data bus and the instruction bus.

1.3.3 External Memory

The ESP32 can access external SPI flash and SPI SRAM as external memory. Table 4 provides a list of external memories that can be accessed by either CPU at a range of addresses on the data and instruction buses. When a CPU accesses external memory through the Cache and MMU, the cache will map the CPU's address to an external physical memory address (in the external memory's address space), according to the MMU settings. Due to this address mapping, the ESP32 can address up to 16 MB External Flash and 8 MB External SRAM.

Table 4: External Memory Address Mapping

1.3.4 Peripherals

The ESP32 has 41 peripherals. Table 5 specifically describes the peripherals and their respective address ranges. Nearly all peripheral modules can be accessed by either CPU at the same address with just a single exception; this being the PID Controller.

1.3.4.1 Asymmetric PID Controller Peripheral

There are two PID Controllers in the system. They serve the PRO_CPU and the APP_CPU, respectively. **The PRO_CPU and the APP_CPU can only access their own PID Controller and not that of their counterpart.** Each CPU uses the same memory range 0x3FF1_F000 ~ 3FF1_FFFF to access its own PID Controller.

1.3.4.2 Non-Contiguous Peripheral Memory Ranges

The SDIO Slave peripheral consists of three parts and the two CPUs use non-contiguous addresses to access these. The three parts are accessed at the address ranges 0x3FF4_B000 ~ 3FF4_BFFF, 0x3FF5_5000 ~ 3FF5_5FFF and 0x3FF5_8000 ~ 3FF5_8FFF of each CPU's data bus. Similarly to other peripherals, access to this peripheral is identical for both CPUs.

1.3.4.3 Memory Speed

The ROM as well as the SRAM are both clocked from CPU_CLK and can be accessed by the CPU in a single cycle. The RTC FAST memory is clocked from the APB_CLOCK and the RTC SLOW memory from the FAST_CLOCK, so access to these memories may be slower. DMA uses the APB_CLK to access memory.

Internally, the SRAM is organized in 32K-sized banks. Each CPU and DMA channel can simultaneously access the SRAM at full speed, provided they access addresses in different memory banks.

2. Interrupt Matrix

2.1 Introduction

The Interrupt Matrix embedded in the ESP32 independently allocates peripheral interrupt sources to the two CPUs' peripheral interrupts. This configuration is made to be highly flexible in order to meet many different needs.

2.2 Features

- Accepts 71 peripheral interrupt sources as input.
- Generates 26 peripheral interrupt sources per CPU as output (52 total).
- CPU NMI Interrupt Mask.
- Queries current interrupt status of peripheral interrupt sources.

The structure of the Interrupt Matrix is shown in Figure 3.

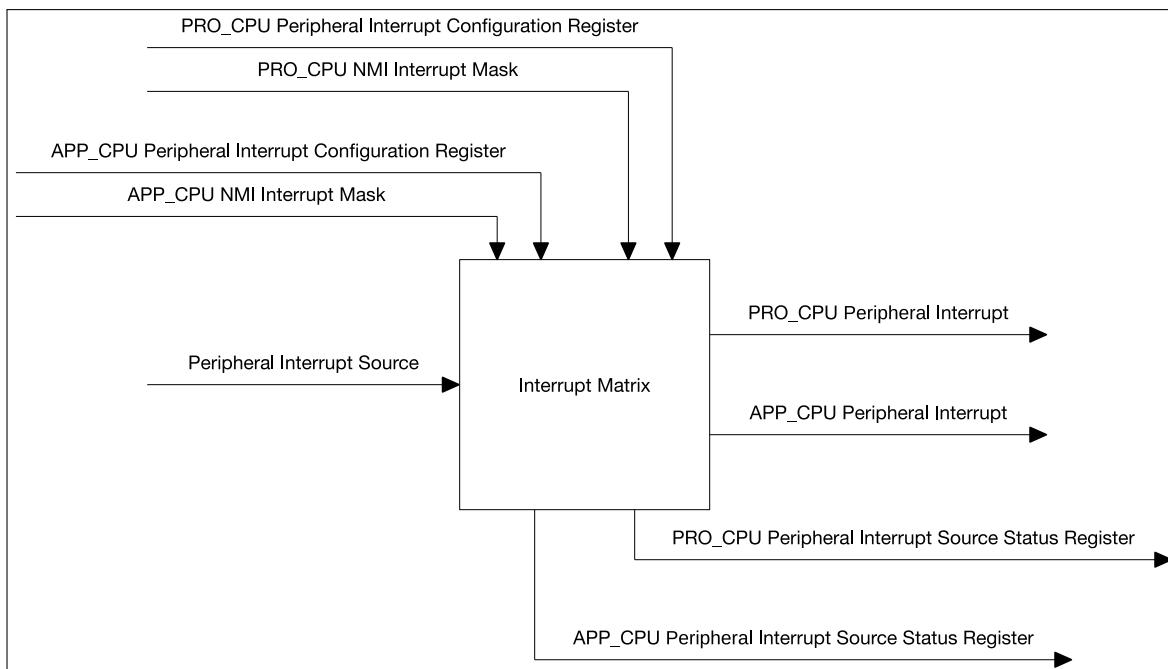

Figure 3: Interrupt Matrix Structure

2.3 Functional Description

2.3.1 Peripheral Interrupt Source

ESP32 has 71 peripheral interrupt sources in total. All peripheral interrupt sources are listed in table 6. 67 of 71 ESP32 peripheral interrupt sources can be allocated to either CPU.

The four remaining peripheral interrupt sources are CPU-specific, two per CPU. GPIO_INTERRUPT_PRO and GPIO_INTERRUPT_PRO_NMI can only be allocated to PRO_CPU. GPIO_INTERRUPT_APP and

GPIO_INTERRUPT_APP_NMI can only be allocated to APP_CPU. As a result, PRO_CPU and APP_CPU each have 69 peripheral interrupt sources.

2.3.3 Allocate Peripheral Interrupt Sources to Peripheral Interrupt on CPU

In this section:

- Source_X stands for any particular peripheral interrupt source.
- PRO_X_MAP_REG (or APP_X_MAP_REG) stands for any particular peripheral interrupt configuration

register of the PRO_CPU (or APP_CPU). The peripheral interrupt configuration register corresponds to the peripheral interrupt source Source_X. In Table 6 the registers listed under “PRO_CPU (APP_CPU) - Peripheral Interrupt Configuration Register” correspond to the peripheral interrupt sources listed in “Peripheral Interrupt Source - Name”.

- Interrupt_P stands for CPU peripheral interrupt, numbered as Num_P. Num_P can take the ranges 0 ~ 5, 8 ~ 10, 12 ~ 14, 17 ~ 28, 30 ~ 31.
- Interrupt_I stands for the CPU internal interrupt numbered as Num_I. Num_I can take values 6, 7, 11, 15, 16, 29.

Using this terminology, the possible operations of the Interrupt Matrix controller can be described as follows:

- **Allocate peripheral interrupt source Source_X to CPU (PRO_CPU or APP_CPU)**
Set PRO_X_MAP_REG or APP_X_MAP_REG to Num_P. Num_P can be any CPU peripheral interrupt number. CPU interrupts can be shared between multiple peripherals (see below).
- **Disable peripheral interrupt source Source_X for CPU (PRO_CPU or APP_CPU)**
Set PRO_X_MAP_REG or APP_X_MAP_REG for peripheral interrupt source to any Num_I. The specific choice of internal interrupt number does not change behaviour, as none of the interrupt numbered as Num_I is connected to either CPU.
- **Allocate multiple peripheral sources Source_Xn ORed to PRO_CPU (APP_CPU) peripheral interrupt**
Set multiple PRO_Xn_MAP_REG (APP_Xn_MAP_REG) to the same Num_P. Any of these peripheral interrupts will trigger CPU Interrupt_P.

2.3.4 CPU NMI Interrupt Mask

The Interrupt Matrix temporarily masks all peripheral interrupt sources allocated to PRO_CPU's (or APP_CPU's) NMI interrupt, if it receives the signal PRO_CPU NMI Interrupt Mask (or APP_CPU NMI Interrupt Mask) from the peripheral PID Controller, respectively.

2.3.5 Query Current Interrupt Status of Peripheral Interrupt Source

The current interrupt status of a peripheral interrupt source can be read via the bit value in PRO_INTR_STATUS_REG_n (APP_INTR_STATUS_REG_n), as shown in the mapping in Table 6.

3. Reset and Clock

3.1 System Reset

3.1.1 Introduction

The ESP32 has three reset levels: CPU reset, Core reset, and System reset. None of these reset levels clear the RAM. Figure 4 shows the subsystems included in each reset level.

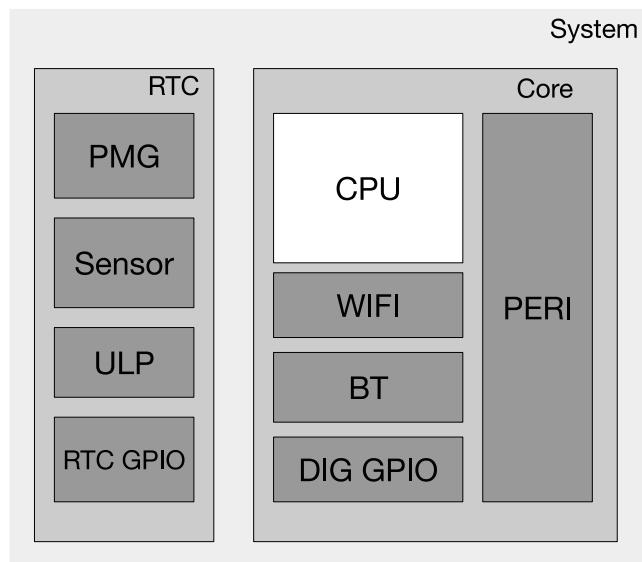

Figure 4: System Reset

- CPU reset: Only resets the registers of one or both of the CPU cores.
- Core reset: Resets all the digital registers, including CPU cores, external GPIO and digital GPIO. The RTC is not reset.
- System reset: Resets all the registers on the chip, including those of the RTC.

3.1.2 Reset Source

While most of the time the APP_CPU and PRO_CPU will be reset simultaneously, some reset sources are able to reset only one of the two cores. The reset reason for each core can be looked up individually: the PRO_CPU reset reason will be stored in RTC_CNTL_RESET_CAUSE_PROCPU, the reset reason for the APP_CPU in APP_CNTL_RESET_CAUSE_PROCPU. Table 8 shows the possible reset reason values that can be read from these registers.

3.2 System Clock

3.2.1 Introduction

The ESP32 integrates multiple clock sources for the CPU cores, the peripherals and the RTC. These clocks can be configured to meet different requirements. Figure 5 shows the system clock structure.

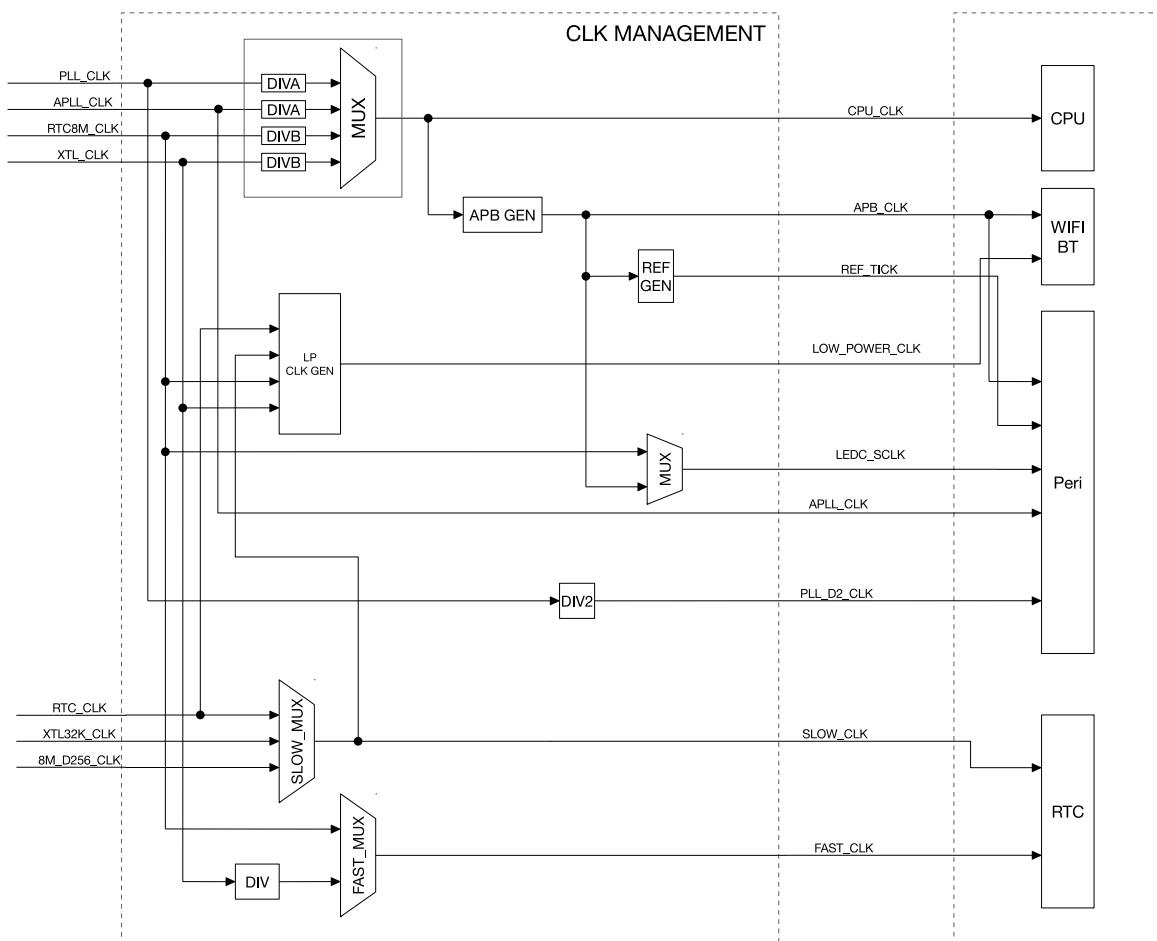

Figure 5: System Clock

3.2.2 Clock Source

The ESP32 can use an external crystal oscillator, an internal PLL or an oscillating circuit as a clock source. Specifically, the clock sources available are:

- High Speed Clocks
 - PLL_CLK is an internal PLL clock with a frequency of 320 MHz.
 - XTL_CLK is a clock signal generated using an external crystal with a frequency range of 2 ~ 40 MHz.
- Low Power Clocks
 - XTL32K_CLK is a clock generated using an external crystal with a frequency of 32 KHz.
 - RTC8M_CLK is an internal clock with a default frequency of 8 MHz. This frequency is adjustable.
 - RTC8M_D256_CLK is divided from RTC8M_CLK 256. Its frequency is (RTC8M_CLK / 256). With the default RTC8M_CLK frequency of 8 MHz, this clock runs at 31.250 KHz.
 - RTC_CLK is an internal low power clock with a default frequency of 150 KHz. This frequency is adjustable.
- Audio Clock
 - APLL_CLK is an internal Audio PLL clock with a frequency range of 16 ~ 128 MHz.

3.2.3 CPU Clock

As Figure 5 shows, CPU_CLK is the master clock for both CPU cores. CPU_CLK clock can be as high as 160 MHz when the CPU is in high performance mode. Alternatively, the CPU can run at lower frequencies to reduce power consumption.

The CPU_CLK clock source is determined by the RTC_CNTL_SOC_CLK_SEL register. PLL_CLK, APLL_CLK, RTC8M_CLK and XTL_CLK can be set as the CPU_CLK source; see Table 9 and 10.

Table 9: CPU_CLK Source

3.2.4 Peripheral Clock

Peripheral clocks include APB_CLK, REF_TICK, LEDC_SCLK, APLL_CLK and PLL_D2_CLK.

Table 11 shows which clocks can be used by which peripherals.

Table 11: Peripheral Clock Usage

Peripherals	APB_CLK	REF_TICK	LEDC_SCLK	APLL_CLK	PLL_D2_CLK

PCNT	Y	N	N	N	N
Efuse Controller	Y	N	N	N	N
SDIO Slave	Y	N	N	N	N
SDMMC	Y	N	N	N	N

3.2.4.1 APB_CLK Source

The APB_CLK is derived from CPU_CLK as detailed in Table 12. The division factor depends on the CPU_CLK source.

Table 12: APB_CLK Derivation

CPU_CLK Source	APB_CLK
PLL_CLK	PLL_CLK / 4
APLL_CLK	CPU_CLK / 2
XTAL_CLK	CPU_CLK
RTC8M_CLK	CPU_CLK

3.2.4.2 REF_TICK Source

REF_TICK is derived from APB_CLK via a divider. The divider value used depends on the APB_CLK source, which in turn depends on the CPU_CLK source.

By configuring correct divider values for each APB_CLK source, the user can ensure that the REF_TICK frequency does not change when CPU_CLK changes source, causing the APB_CLK frequency to change.

Clock divider registers are shown in Table 13.

Table 13: REF_TICK Derivation

CPU_CLK & APB_CLK Source	Clock Divider Register
PLL_CLK	APB_CTRL_PLL_TICK_NUM
XTAL_CLK	APB_CTRL_XTAL_TICK_NUM
APLL_CLK	APB_CTRL_APOLL_TICK_NUM
RTC8M_CLK	APB_CTRL_CK8M_TICK_NUM

3.2.4.3 LEDC_SCLK Source

The LEDC_SCLK clock source is selected by the LEDC_APB_CLK_SEL register, as shown in Table 14.

Table 14: LEDC_SCLK Derivation

LEDC_APB_CLK_SEL Value	LEDC_SCLK Source
1	RTC8M_CLK
0	APB_CLK

3.2.4.4 APOLL_SCLK Source

The APOLL_CLK is sourced from PLL_CLK, with its output frequency configured using the APOLL configuration registers.

3.2.4.5 PLL_D2_CLK Source

PLL_D2_CLK is half the PLL_CLK frequency.

3.2.4.6 Clock Source Considerations

Most peripherals will operate using the APB_CLK frequency as a reference. When this frequency changes, the peripherals will need to update their clock configuration to operate at the same frequency after the change. Peripherals accessing REF_TICK can continue operating normally when switching clock sources, without changing clock source. Please see Table 11 for details.

The LED PWM module can use RTC8M_CLK as a clock source when APB_CLK is disabled. In other words, when the system is in low-power consumption mode (see power manager module), normal peripherals will be halted (APB_CLK is turned off), but the LED PWM can work normally via RTC8M_CLK.

3.2.5 Wi-Fi BT Clock

Wi-Fi and BT can only operate if APB_CLK uses PLL_CLK as its clock source. Suspending PLL_CLK requires Wi-Fi and BT to both have entered low-power consumption mode first.

For LOW_POWER_CLK, one of RTC_CLK, [SLOW_CLK](#), RTC8M_CLK or XTL_CLK can be selected as the low-power consumption mode clock source for Wi-Fi and BT.

3.2.6 RTC Clock

The clock sources of SLOW_CLK and FAST_CLK are low-frequency clocks. The RTC module can operate when most other clocks are stopped.

SLOW_CLK is used to clock the Power Management module. It can be sourced from RTC_CLK, XTL32K_CLK or RTC8M_D256_CLK

FAST_CLK is used to clock the On-chip Sensor module. It can be sourced from a divided XTL_CLK or from RTC8M_CLK.

4. IO_MUX and GPIO Matrix

4.1 Introduction

The ESP32 chip features 40 physical GPIO pads. Some GPIO pads can neither be used nor have the corresponding pins on the chip package. Each pad can be used as a general-purpose I/O, or be connected to an internal peripheral signal. The IO_MUX, RTC IO_MUX and the GPIO matrix are responsible for routing signals from the peripherals to GPIO pads. Together these systems provide highly configurable I/O.

This chapter describes the signal selection and connection between the digital pads (FUNC_SEL, IE, OE, WPU, WDU, etc), 256 peripheral input/output signals (control signals: SIG_IN_SEL, SIG_OUT_SEL, IE, OE, etc), fast peripheral input/output signals (control signals: IE, OE, etc), and RTC IO_MUX.

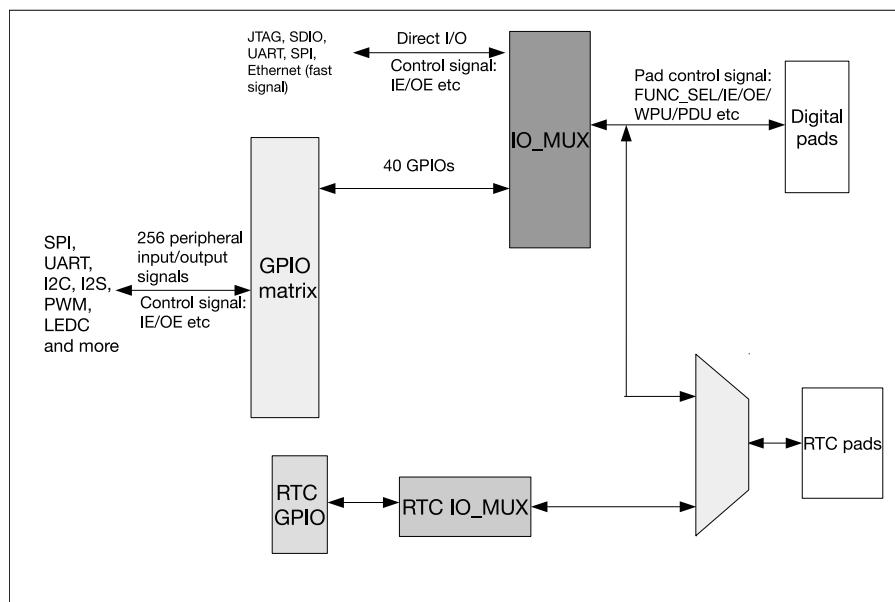

Figure 6: IO_MUX, RTC IO_MUX and GPIO Matrix Overview

1. The IO_MUX contains one register per GPIO pad. Each pad can be configured to perform a "GPIO" function (when connected to the GPIO Matrix) or a direct function (bypassing the GPIO Matrix). Some high-speed digital functions (Ethernet, SDIO, SPI, JTAG, UART) can bypass the GPIO Matrix for better high-frequency digital performance. In this case, the IO_MUX is used to connect these pads directly to the peripheral.)

See Section 4.10 for a list of IO_MUX functions for each I/O pad.

2. The GPIO Matrix is a full-switching matrix between the peripheral input/output signals and the pads.

- For input to the chip: Each of the 256 internal peripheral inputs can select any GPIO pad as the input source.
- For output from the chip: The output signal of each of the 40 GPIO pads can be from one of the 256 peripheral output signals.

See Section 4.9 for a list of GPIO Matrix peripheral signals.

3. RTC IO_MUX is used to connect GPIO pads to their low-power and analog functions. Only a subset of GPIO pads have these optional "RTC" functions.

See Section 4.11 for a list of RTC IO_MUX functions.

4.2 Peripheral Input via GPIO Matrix

4.2.1 Summary

To receive a peripheral input signal via the GPIO Matrix, the GPIO Matrix is configured to source the peripheral signal's input index (0-255) from one of the 40 GPIOs (0-39).

The input signal is read from the GPIO pad through the IO_MUX. The IO_MUX must be configured to set the chosen pad to "GPIO" function. This causes the GPIO pad input signal to be routed into the GPIO Matrix, which in turn routes it to the selected peripheral input.

4.2.2 Functional Description

Figure 7 shows the logic for input selection via GPIO Matrix.

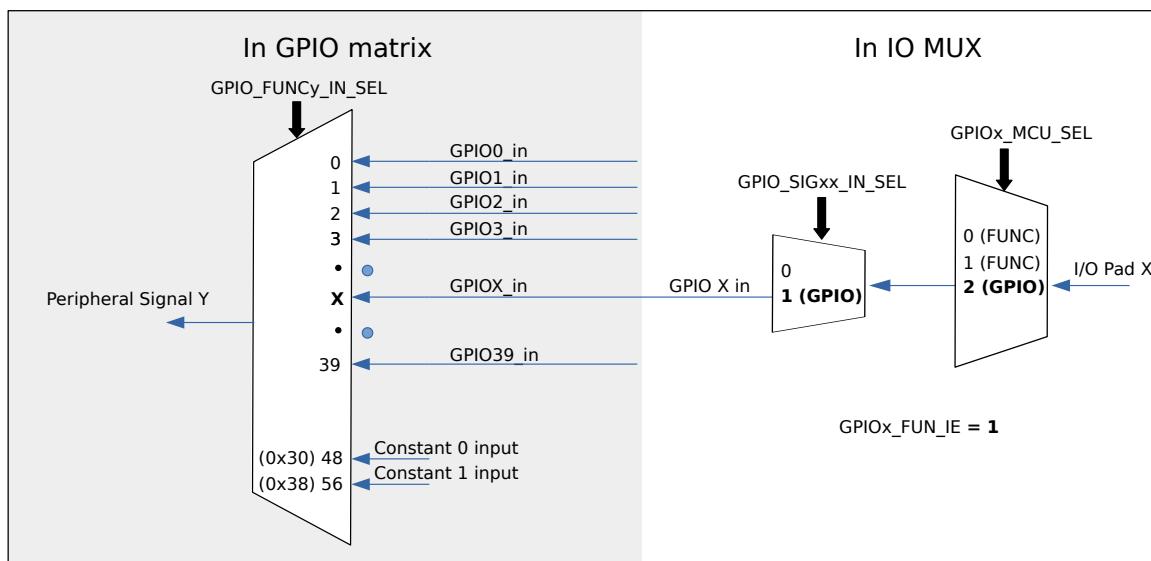

Figure 7: Peripheral Input via IO_MUX, GPIO Matrix

To read GPIO pad X into peripheral signal Y , follow the steps below:

1. Configure the `GPIO_FUNCy_IN_SEL_CFG` register for peripheral signal Y in the GPIO Matrix:
 - Set the `GPIO_FUNCx_IN_SEL` field to the number of the GPIO pad X to read from.
2. Configure the `GPIO_FUNCx_OUT_SEL_CFG` and `GPIO_ENABLE_DATA[x]` for GPIO pad X in the GPIO Matrix:
 - For input only signals, the pad output can be disabled by setting the `GPIO_FUNCx_OEN_SEL` bits to one and `GPIO_ENABLE_DATA[x]` to zero. Otherwise, there is no need to disable output.
3. Configure the IO_MUX register for GPIO pad X :
 - Set the function field to GPIO.
 - Enable the input by setting the `xx_FUN_IE` bit.
 - Set `xx_FUN_WPU` and `xx_FUN_WPD` fields, as desired, to enable internal pull-up/pull-down resistors.

Notes:

- One input pad can be connected to multiple input_signals.

- The input signal can be inverted with GPIO_FUNC x _IN_INV_SEL.
- It is possible to have a peripheral read a constantly low or constantly high input value without connecting this input to a pad. This can be done by selecting a special GPIO_FUNC y _IN_SEL input, instead of a GPIO number:
 - When GPIO_FUNC x _IN_SEL is 0x30, input_signal $_x$ is always 0.
 - When GPIO_FUNC x _IN_SEL is 0x38, input_signal $_x$ is always 1.

4.2.3 Simple GPIO Input

The GPIO_IN_DATA register holds the input values of each GPIO pad.

The input value of any GPIO pin can be read at any time without configuring the GPIO Matrix for a particular peripheral signal. However, it is necessary to configure the xx_FUN_IE register for pad X , as shown in Section 4.2.2.

4.3 Peripheral Output via GPIO Matrix

4.3.1 Summary

To output a signal from a peripheral via the GPIO Matrix, the GPIO Matrix is configured to route the peripheral output signal (0-255) to one of the first 34 GPIOs (0-33). (Note that GPIO pads 34-39 cannot be used as outputs.)

The output signal is routed from the peripheral into the GPIO Matrix. It is then routed into the IO_MUX, which is configured to set the chosen pad to "GPIO" function. This causes the output GPIO signal to be connected to the pad.

4.3.2 Functional Description

One of 256 input signals can be selected to go through the GPIO matrix into the IO_MUX and then to a pad.

Figure 8 illustrates the configuration.

To output peripheral signal Y to particular GPIO pad X , follow these steps:

1. Configure the GPIO_FUNC x _OUT_SEL_CFG register and GPIO_ENABLE_DATA[x] of GPIO X in the GPIO Matrix:
 - Set GPIO_FUNC x _OUT_SEL to the index of desired peripheral output signal Y .
 - Set the GPIO_FUNC x _OEN_SEL bits and GPIO_ENABLE_DATA[x] to enable output mode, or clear GPIO_FUNC x _OEN_SEL to zero so that the output enable signal will be decided by the internal logic function.
2. Alternatively, to enable open drain mode set the GPIO_PIN x _PAD_DRIVER bit in the GPIO_PIN x register.
3. Configure the I/O mux register for GPIO pad X :
 - Set the function field to GPIO.
 - Set the xx_FUN_DRV field to the desired value for output strength. The higher the value is, the stronger the output becomes. Pull up/down the pad by configuring xx_FUNC_WPU and xx_FUNC_WPD registers in open drain mode.

Notes:

- The output signal from a single peripheral can be sent to multiple pads simultaneously.
- Only the first 34 GPIOs (0-33) can be used as outputs.
- The output signal can be inverted by setting the `GPIO_FUNCx_OUT_INV_SEL` bit.

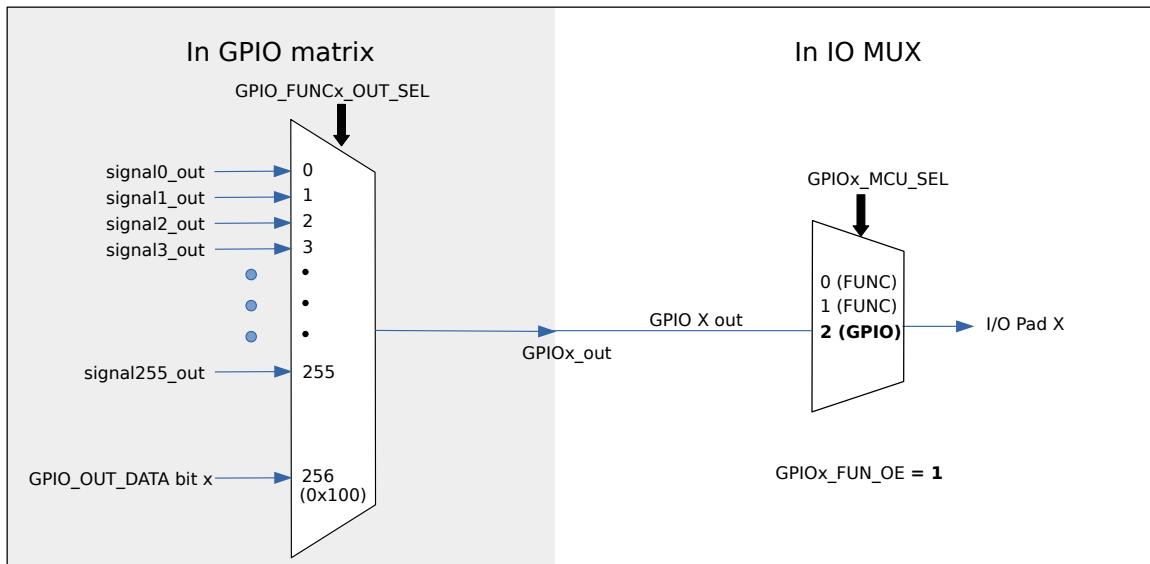

Figure 8: Output via GPIO Matrix

4.3.3 Simple GPIO Output

The GPIO Matrix can also be used for simple GPIO output - setting a bit in the `GPIO_OUT_DATA` register will write to the corresponding GPIO pad.

To configure a pad as simple GPIO output, the GPIO Matrix `GPIO_FUNCx_OUT_SEL` register is configured with a special peripheral index value (0x100).

4.4 Direct I/O via IO_MUX

4.4.1 Summary

Some high speed digital functions (Ethernet, SDIO, SPI, JTAG, UART) can bypass the GPIO Matrix for better high-frequency digital performance. In this case, the IO_MUX is used to connect these pads directly to the peripheral.

Selecting this option is less flexible than using the GPIO Matrix, as the IO_MUX register for each GPIO pad can only select from a limited number of functions. However, better high-frequency digital performance will be maintained.

4.4.2 Functional Description

Two registers must be configured in order to bypass the GPIO Matrix for peripheral I/O:

1. IO_MUX for the GPIO pad must be set to the desired pad function (Section 4.10 has a list of pad functions).
2. For inputs, the `SIG_IN_SEL` register must be set to route the input directly to the peripheral.

4.5 RTC IO_MUX for Low Power and Analog I/O

4.5.1 Summary

Out of the 40 physical GPIO pads, 18 pads have low power capabilities (RTC domain) and analog functions which are handled by the RTC subsystem of ESP32. The IO_MUX and GPIO Matrix are not used for these functions; rather, the RTC_MUX is used to redirect the I/O to the RTC subsystem.

When configured as RTC GPIOs, the output pads can still retain the output level value when the chip is in Deep-sleep mode, and the input pads can wake up the chip from Deep-sleep.

Section [4.11](#) has a list of RTC_MUX pins and their functions.

4.5.2 Functional Description

Each pad with analog and RTC functions is controlled by the RTC_IO_TOUCH_PAD_x_TO_GPIO bit in the RTC_GPIO_PIN_x register. By default this bit is set to 1, routing all I/O via the IO_MUX subsystem as described in earlier subsections.

If the RTC_IO_TOUCH_PAD_x_TO_GPIO bit is cleared, then I/O to and from that pad is routed to the RTC subsystem. In this mode, the RTC_GPIO_PIN_x register is used for digital I/O and the analog features of the pad are also available. See Section [4.11](#) for a list of RTC pin functions.

See [4.11](#) for a table mapping GPIO pads to their RTC equivalent pins and analog functions. Note that the RTC_IO_PIN_x registers use the RTC GPIO pin numbering, not the GPIO pad numbering.

4.6 Light-sleep Mode Pin Functions

Pins can have different functions when the ESP32 is in Light-sleep mode. If the GPIO_{xx}_SLP_SEL bit in the IO_MUX register for a GPIO pad is set to 1, a different set of registers is used to control the pad when the ESP32 is in Light-sleep mode:

Table 15: IO_MUX Light-sleep Pin Function Registers

IO_MUX Function	Normal Execution OR GPIO _{xx} _SLP_SEL = 0	Light-sleep Mode AND GPIO _{xx} _SLP_SEL = 1
Output Drive Strength	GPIO _{xx} _FUNC_DRV	GPIO _{xx} _MCU_DRV
Pullup Resistor	GPIO _{xx} _FUNC_WPU	GPIO _{xx} _MCU_WPU
Pulldown Resistor	GPIO _{xx} _FUNC_WPD	GPIO _{xx} _MCU_WPD
Output Enable	(From GPIO Matrix _OEN field)	GPIO _{xx} _MCU_OE

If GPIO_{xx}_SLP_SEL is set to 0, the pin functions remain the same in both normal execution and Light-sleep modes.

4.7 Pad Hold Feature

Each IO pad (including the RTC pads) has an individual hold function controlled by a RTC register. When the pad is set to hold, the state is latched at that moment and will not change no matter how the internal signals change or how the IO_MUX configuration or GPIO configuration is modified. Users can use the hold function for the pads

to retain the pad state through a core reset and system reset triggered by watchdog time-out or Deep-sleep events.

4.8 I/O Pad Power Supply

IO pad power supply is shown in Figure 9.

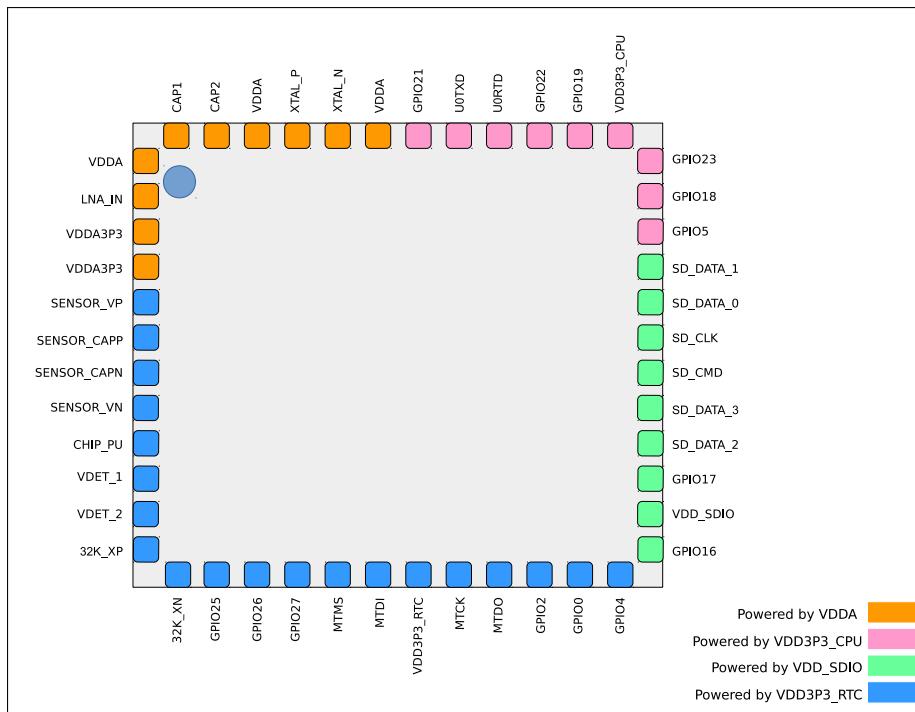

Figure 9: ESP32 I/O Pad Power Sources

- Pads marked blue are RTC pads that have their individual analog function and can also act as normal digital IO pads. For details, please see Section 4.11.
- Pads marked pink and green have digital functions only.
- Pads marked green can be powered externally or internally via VDD_SDIO (see below).

4.8.1 VDD_SDIO Power Domain

VDD_SDIO can source or sink current, allowing this power domain to be powered externally or internally. To power VDD_SDIO externally, apply the same power supply of VDD3P3_RTC to the VDD_SDIO pad.

Without an external power supply, the internal regulator will supply VDD_SDIO. The VDD_SDIO voltage can be configured to be either 1.8V or 3.3V (the same as that at VRTC), depending on the state of the MTDI pad at reset - a high level configures 1.8V and a low level configures 3.3V. Setting the efuse bit determines the default voltage of the VDD_SDIO. In addition, software can change the voltage of the VDD_SDIO by configuring register bits.

Direct I/O in IO_MUX "YES" means that this signal is also available directly via IO_MUX. To apply the GPIO Matrix to these signals, their corresponding SIG_IN_SEL register must be cleared.

Reset Configurations

"Reset" column shows each pad's default configurations after reset:

- **0** - IE=0 (input disabled).
- **1** - IE=1 (input enabled).
- **2** - IE=1, WPD=1 (input enabled, pulldown resistor).
- **3** - IE=1, WPU=1 (input enabled, pullup resistor).

Notes

- **R** - Pad has RTC/analog functions via RTC_MUX.
- **I** - Pad can only be configured as input GPIO.

Refer to [ESP32 Pin List](#) datasheet for more details and a complete table of pin functions.

4.13 Registers

Register 4.1: GPIO_OUT_REG (0x0004)

GPIO_OUT_REG GPIO0-31 output value. (R/W)

Register 4.2: GPIO_OUT_W1TS_REG (0x0008)

GPIO_OUT_W1TS_REG GPIO0-31 output set register. For every bit that is 1 in the value written here, the corresponding bit in GPIO OUT DATA will be set. (RO)

Register 4.3: GPIO_OUT_W1TC_REG (0x000c)

GPIO_OUT_W1TC_REG GPIO0-31 output clear register. For every bit that is 1 in the value written here, the corresponding bit in GPIO_OUT_DATA will be cleared. (RO)

Register 4.4: GPIO_OUT1_REG (0x0010)

The diagram shows the bit layout of the GPIO_OUT_DATA register. It consists of two main sections: a left section labeled '(reserved)' and a right section labeled 'GPIO_OUT_DATA'. The left section contains 32 bits, indexed from 31 to 0. The right section contains 8 bits, indexed from 7 to 0. The 'Reset' value is shown as all 'x' characters.

GPIO_OUT_DATA GPIO32-39 output value. (R/W)

Register 4.5: GPIO_OUT1_W1TS_REG (0x0014)

GPIO_OUT_DATA GPIO32-39 output value set register. For every bit that is 1 in the value written here, the corresponding bit in GPIO_OUT1_DATA will be set. (RO)

Register 4.6: GPIO_OUT1_W1TC_REG (0x0018)

GPIO_OUT_DATA GPIO32-39 output value clear register. For every bit that is 1 in the value written here, the corresponding bit in GPIO_OUT1_DATA will be cleared. (RO)

Register 4.7: GPIO_ENABLE_REG (0x0020)

GPIO_ENABLE_REG GPIO0-31 output enable. (R/W)

Register 4.8: GPIO_ENABLE_W1TS_REG (0x0024)

GPIO_ENABLE_W1TS_REG GPIO0-31 output enable set register. For every bit that is 1 in the value written here, the corresponding bit in GPIO_ENABLE will be set. (RO)

Register 4.9: GPIO_ENABLE_W1TC_REG (0x0028)

GPIO_ENABLE_W1TC_REG GPIO0-31 output enable clear register. For every bit that is 1 in the value written here, the corresponding bit in GPIO_ENABLE will be cleared. (RO)

Register 4.10: GPIO_ENABLE1_REG (0x002c)

GPIO_ENABLE_DATA GPIO32-39 output enable. (R/W)

Register 4.11: GPIO_ENABLE1_W1TS_REG (0x0030)

GPIO_ENABLE_DATA GPIO32-39 output enable set register. For every bit that is 1 in the value written here, the corresponding bit in GPIO_ENABLE1 will be set. (RO)

Register 4.12: GPIO_ENABLE1_W1TC_REG (0x0034)

GPIO_ENABLE_DATA GPIO32-39 output enable clear register. For every bit that is 1 in the value written here, the corresponding bit in GPIO_ENABLE1 will be cleared. (RO)

Register 4.13: GPIO STRAP REG (0x0038)

GPIO_STRAPPING GPIO strapping results: boot_sel_chip[5:0]: MTDI, GPIO0, GPIO2, GPIO4, MTDO, GPIO5

Register 4.14: GPIO_IN_REG (0x003c)

GPIO_IN_REG GPIO0-31 input value. Each bit represents a pad input value, 1 for high level and 0 for low level. (RO)

Register 4.15: GPIO_IN1_REG (0x0040)

GPIO_IN_DATA_NEXT GPIO32-39 input value. Each bit represents a pad input value. (RO)

Register 4.16: GPIO_STATUS_REG (0x0044)

GPIO_STATUS_REG GPIO0-31 interrupt status register. Each bit can be either of the two interrupt sources for the two CPUs. The enable bits in GPIO_STATUS_INTERRUPT, corresponding to the 0-4 bits in GPIO_PIN n REG should be set to 1. (R/W)

Register 4.17: GPIO_STATUS_W1TS_REG (0x0048)

GPIO_STATUS_W1TS_REG GPIO0-31 interrupt status set register. For every bit that is 1 in the value written here, the corresponding bit in GPIO_STATUS_INTERRUPT will be set. (RO)

Register 4.18: GPIO_STATUS_W1TC_REG (0x004c)

GPIO_STATUS_W1TC_REG GPIO0-31 interrupt status clear register. For every bit that is 1 in the value written here, the corresponding bit in GPIO STATUS INTERRUPT will be cleared. (RO)

Register 4.19: GPIO_STATUS1_REG (0x0050)

The diagram shows the memory map for the `GPIO_STATUS_INTERRUPT` register. It consists of a single horizontal row of 32 bits. The bit labels are: 31, (reserved), 8, 7, 0, and Reset. The bits from 31 to 7 are all set to 0. Bit 0 is labeled `x`. The label `Reset` is positioned at the far right end of the row.

31	(reserved)	8	7	0	Reset
0	0	0	0	0	

GPIO_STATUS_INTERRUPT GPIO32-39 interrupt status. (R/W)

Register 4.20: GPIO_STATUS1_W1TS_REG (0x0054)

The diagram shows the memory map for the GPIO_STATUS_INTERRUPT register. It consists of a single horizontal row of 32 bits. The bit range from 31 to 0 is shown at the top. Bit 31 is labeled "31" and bit 0 is labeled "0". Between bit 31 and bit 0, there is a label "(reserved)" with a diagonal line through it. To the right of the bit range, there is a vertical label "GPIO_STATUS_INTERRUPT" rotated diagonally. Below the bit range, each bit position has a small square box containing either an "x" or a "0". The bits are grouped into four columns: bits 31-24, bits 23-16, bits 15-8, and bits 7-0. The first column (bits 31-24) contains all "x"s. The second column (bits 23-16) contains all "0"s. The third column (bits 15-8) contains "x"s in the positions of bit 15, bit 13, bit 11, bit 9, and bit 7. The fourth column (bits 7-0) contains "x"s in the positions of bit 6, bit 4, bit 2, and bit 0.

GPIO_STATUS_INTERRUPT GPIO32-39 interrupt status set register. For every bit that is 1 in the value written here, the corresponding bit in GPIO_STATUS_INTERRUPT1 will be set. (RO)

Register 4.21: GPIO_STATUS1_W1TC_REG (0x0058)

GPIO_STATUS_INTERRUPT GPIO32-39 interrupt status clear register. For every bit that is 1 in the value written here, the corresponding bit in GPIO_STATUS_INTERRUPT1 will be cleared. (RO)

Register 4.22: GPIO_ACPU_INT_REG (0x0060)

GPIO ACPU INT REG GPIO0-31 APP CPU interrupt status. (RO)

Register 4.23: GPIO_ACPU_NMI_INT_REG (0x0064)

GPIO_ACPU_NMI_INT_REG GPIO0-31 APP CPU non-maskable interrupt status. (RO)

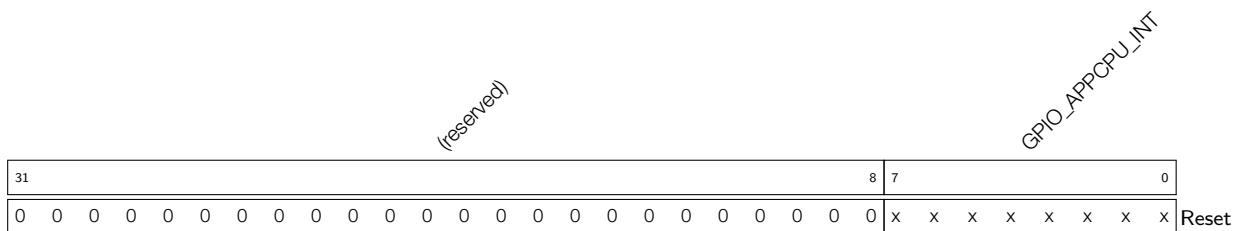

Register 4.24: GPIO_PCPU_INT_REG (0x0068)

GPIO_PCPU_INT_REG GPIO0-31 PRO CPU interrupt status. (RO)

Register 4.25: GPIO_PCPU_NMI_INT_REG (0x006c)

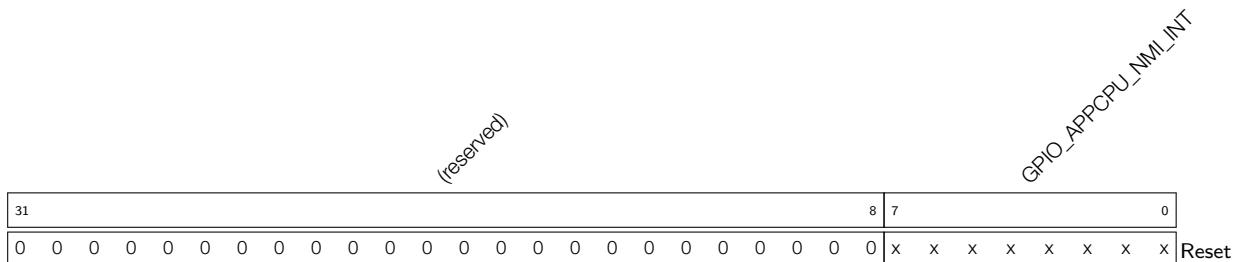

GPIO_PCPU_NMI_INT_REG GPIO0-31 PRO CPU non-maskable interrupt status. (RO)

Register 4.26: GPIO_ACPU_INT1_REG (0x0074)

GPIO_APPCPU_INT GPIO32-39 APP CPU interrupt status. (RO)

Register 4.27: GPIO_ACPU_NMI_INT1_REG (0x0078)

GPIO_APPCPU_NMI_INT GPIO32-39 APP CPU non-maskable interrupt status. (RO)

Register 4.28: GPIO_PCPU_INT1_REG (0x007c)

GPIO_PROCPU_INT GPIO32-39 PRO CPU interrupt status. (RO)

Register 4.29: GPIO_PCPU_NMI_INT1_REG (0x0080)

GPIO_PROCPU_NMI_INT GPIO32-39 PRO CPU non-maskable interrupt status. (RO)

Register 4.30: GPIO_PIN n _REG (n : 0-39) (0x88+0x4* n)

GPIO_PIN n _INT_ENA Interrupt enable bits for pin n : (R/W)

bit0: APP CPU interrupt enable;

bit1: APP CPU non-maskable interrupt enable;

bit3: PRO CPU interrupt enable;

bit4: PRO CPU non-maskable interrupt enable.

GPIO_PIN_n_WAKEUP_ENABLE GPIO wake-up enable will only wake up the CPU from Light-sleep.
(R/W)

GPIO_PIN_n_INT_TYPE Interrupt type selection: (R/W)

0: GPIO interrupt disable;

1: rising edge trigger;

2: falling edge trigger;

3: any edge trigger;

4: low level trigger;

5: high level trigger.

GPIO PIN_n PAD DRIVER 0: normal output; 1: open drain output. (R/W)

Register 4.31: GPIO_FUNC m _IN_SEL_CFG_REG (m : 0-255) (0x130+0x4* m)

31	(reserved)								8	7	6	5	0		
0	0	0	0	0	0	0	0	0	0	x	x	x	x	x	Reset

GPIO_SIG m _IN_SEL Bypass the GPIO Matrix. 0: route through GPIO Matrix, 1: connect signal directly to peripheral configured in the IO MUX. (R/W)

GPIO FUNC_m IN INV SEL Invert the input value. 1: invert; 0: do not invert. (R/W)

GPIO_FUNC m _IN_SEL Selection control for peripheral input m . A value of 0-39 selects which of the 40 GPIO Matrix input pins this signal is connected to, or 0x38 for a constantly high input or 0x30 for a constantly low input. (R/W)

Register 4.32: GPIO_FUNC n _OUT_SEL_CFG_REG (n : 0-39) (0x530+0x4* n)

GPIO_FUNC*n*_OEN_INV_SEL 1: Invert the output enable signal; 0: do not invert the output enable signal. (R/W)

GPIO_FUNC n _OEN_SEL 1: Force the output enable signal to be sourced from bit n of GPIO_ENABLE_REG; 0: use output enable signal from peripheral. (R/W)

GPIO_FUNCn_OUT_INV_SEL 1: Invert the output value; 0: do not invert the output value. (R/W)

GPIO_FUNC n _OUT_SEL Selection control for GPIO output n . A value of s ($0 \leq s < 256$) connects peripheral output s to GPIO output n . A value of 256 selects bit n of GPIO_DATA_REG and GPIO_ENABLE_REG as the output value and output enable. (R/W)

Register 4.33: IO_MUX_X_REG (x: GPIO0-GPIO39) (0x10+4*x)

IO_X MCU_SEL Select the IO_MUX function for this signal. 0 selects Function 1, 1 selects Function 2, etc. (R/W)

IO_X_FUNC_DRV Select the drive strength of the pad. A higher value corresponds with a higher strength. (R/W)

IO_X_FUNC_IE Input enable of the pad. 1: input enabled; 0: input disabled. (R/W)

IO_X_FUNC_WPU Pull-up enable of the pad. 1: internal pull-up enabled; 0: internal pull-up disabled.
(R/W)

IO_X_FUNC_WPD Pull-down enable of the pad. 1: internal pull-down enabled, 0: internal pull-down disabled. (R/W)

IO_X MCU_DRV Select the drive strength of the pad during sleep mode. A higher value corresponds with a higher strength. (R/W)

IO_X_MCU_IE Input enable of the pad during sleep mode. 1: input enabled; 0: input disabled. (R/W)

IO_X MCU_WPU Pull-up enable of the pad during sleep mode. 1: internal pull-up enabled; 0: internal pull-up disabled. (R/W)

IO_X MCU_WPD Pull-down enable of the pad during sleep mode. 1: internal pull-down enabled; 0: internal pull-down disabled. (R/W)

IO_X_SLP_SEL Sleep mode selection of this pad. Set to 1 to put the pad in sleep mode. (R/W)

IO_x MCU_OE Output enable of the pad in sleep mode. 1: enable output; 0: disable output. (R/W)

Register 4.34: RTCIO_RTC_GPIO_OUT_REG (0x0000)

RTCIO_RTC_GPIO_OUT_DATA GPIO0-17 output register. Bit14 is GPIO[0], bit15 is GPIO[1], etc.
(R/W)

Register 4.35: RTCIO_RTC_GPIO_OUT_W1TS_REG (0x0001)

RTCIO_RTC_GPIO_OUT_DATA_W1TS GPIO0-17 output set register. For every bit that is 1 in the value written here, the corresponding bit in RTCIO_RTC_GPIO_OUT will be set. (WO)

Register 4.36: RTCIO_RTC_GPIO_OUT_W1TC_REG (0x0002)

RTCIO_RTC_GPIO_OUT_DATA_W1TC GPIO0-17 output clear register. For every bit that is 1 in the value written here, the corresponding bit in RTCIO_RTC_GPIO_OUT will be cleared. (WO)

Register 4.37: RTCIO RTC GPIO ENABLE REG (0x0003)

The diagram shows the **RTCIO_RTC_GPIO_ENABLE** register structure. It consists of a 32-bit register with the following fields:

- 31**: Bit 31.
- (reserved)**: Bits 27 to 14, labeled as (reserved).
- 14**: Bit 14.
- 27**: Bit 27.
- x**: Bits 31 to 28, all set to x (don't care).
- 0**: Bits 27 to 14, all set to 0.
- Reset**: A label indicating the reset value for the entire register.

RTCIO_RTC_GPIO_ENABLE GPIO0-17 output enable. Bit14 is GPIO[0], bit15 is GPIO[1], etc. 1 means this GPIO pad is output. (R/W)

Register 4.38: RTCIO_RTC_GPIO_ENABLE_W1TS_REG (0x0004)

RTCIO_RTC_GPIO_ENABLE_W1TS GPIO0-17 output enable set register. For every bit that is 1 in the value written here, the corresponding bit in RTCIO RTC GPIO ENABLE will be set. (WO)

Register 4.39: RTCIO_RTC_GPIO_ENABLE_W1TC_REG (0x0005)

RTCIO_RTC_GPIO_ENABLE_W1TC GPIO0-17 output enable clear register. For every bit that is 1 in the value written here, the corresponding bit in RTCIO_RTC_GPIO_ENABLE will be cleared. (WO)

Register 4.40: RTCIO RTC GPIO STATUS REG (0x0006)

RTCIO_RTC_GPIO_STATUS_INT GPIO0-17 interrupt status. Bit14 is GPIO[0], bit15 is GPIO[1], etc. This register should be used together with RTCIO_RTC_GPIO_PIN_n_INT_TYPE in RTCIO_RTC_GPIO_PIN_n_REG. 1: corresponding interrupt; 0: no interrupt. (R/W)

Register 4.41: RTCIO_RTC_GPIO_STATUS_W1TS_REG (0x0007)

RTCIO_RTC_GPIO_STATUS_INT_W1TS GPIO0-17 interrupt set register. For every bit that is 1 in the value written here, the corresponding bit in RTCIO_RTC_GPIO_STATUS_INT will be set. (WO)

Register 4.42: RTCIO_RTC_GPIO_STATUS_W1TC_REG (0x0008)

RTCIO_RTC_GPIO_STATUS_INT_W1TC GPIO0-17 interrupt clear register. For every bit that is 1 in the value written here, the corresponding bit in RTCIO_RTC_GPIO_STATUS_INT will be cleared. (WO)

Register 4.43: RTCIO_RTC_GPIO_IN_REG (0x0009)

RTCIO_RTC_GPIO_IN_NEXT GPIO0-17 input value. Bit14 is GPIO[0], bit15 is GPIO[1], etc. Each bit represents a pad input value, 1 for high level, and 0 for low level. (RO)

Register 4.44: RTCIO_RTC_GPIO_PIN_n_REG (n: 0-17) (0xA+1*n)

The diagram shows the bit field layout for Register 4.44. It consists of a 32-bit register with the following bit assignments:

- Bit 31:** (reserved)
- Bits 11-10:** (reserved)
- Bit 9:** (reserved)
- Bits 7-6:** RTCIO_RTC_GPIO_PIN_n_WAKEUP_ENABLE
- Bit 5:** (reserved)

RTCIO_RTC_GPIO_PIN_n_WAKEUP_ENABLE GPIO wake-up enable. This will only wake up the ESP32 from Light-sleep. (R/W)

RTCIO_RTC_GPIO_PIN_n_INT_TYPE GPIO interrupt type selection. (R/W)

- 0: GPIO interrupt disable;
- 1: rising edge trigger;
- 2: falling edge trigger;
- 3: any edge trigger;
- 4: low level trigger;
- 5: high level trigger.

RTCIO_RTC_GPIO_PIN_n_PAD_DRIVER Pad driver selection. 0: normal output; 1: open drain. (R/W)

Register 4.45: RTCIO_DIG_PAD_HOLD_REG (0x001d)

31	0	0	Reset
0			

RTCIO_DIG_PAD_HOLD_REG Select which digital pads are on hold. While 0 allows normal operation, 1 puts the pad on hold. (R/W)

Register 4.46: RTCIO_HALL_SENS_REG (0x001e)

The diagram shows the bit field layout for Register 4.46. It consists of a 32-bit register with the following bit assignments:

- Bit 31:** RTCIO_HALL_XPD_HALL
- Bit 30:** RTCIO_HALL_PHASE
- Bit 29:** (reserved)
- Bit 28:** (reserved)
- Bit 27:** (reserved)

RTCIO_ADC_ADC n _MUX_SEL 0: route pad to the digital IO_MUX; (R/W)
1: route pad to the RTC block.

RTCIO_ADC_ADC n _FUN_SEL Select the RTC function for this pad. 0: select Function 0; 1: select Function 1. (R/W)

RTCIO_ADC_ADC n _SLP_SEL Signal selection of pad's sleep mode. Set this bit to 1 to put the pad to sleep. (R/W)

RTCIO_ADC_ADC n _SLP_IE Input enable of the pad in sleep mode. 1 enabled; 0 disabled. (R/W)

RTCIO_ADC_ADC n _FUN_IE Input enable of the pad. 1 enabled; 0 disabled. (R/W)

Register 4.49: RTCIO_PAD_DAC1_REG (0x0021)

The register map shows the bit fields for RTCIO_PAD_DAC1_REG. The bits are numbered from 31 to 10. The fields are:

- RTCIO_PAD_PDAC1_DRV (bits 30-29)
- RTCIO_PAD_PDAC1_HOLD (bit 28)
- RTCIO_PAD_PDAC1_RDE (bit 27)
- RTCIO_PAD_PDAC1_RUE (bit 26)
- RTCIO_PAD_PDAC1_DAC (bit 19)
- RTCIO_PAD_PDAC1_XPD_DAC (bit 18)

RTCIO_PAD_PDAC1_HOLD Set to 1 to hold the output value on the pad; set to 0 for normal operation. (R/W)

RTCIO_PAD_PDAC1_RDE 1: Pull-down on pad enabled; 0: Pull-down disabled. (R/W)

RTCIO_PAD_PDAC1_RUE 1: Pull-up on pad enabled; 0: Pull-up disabled. (R/W)

RTCIO_PAD_PDAC1_DAC PAD DAC1 output value. (R/W)

RTCIO_PAD_PDAC1_XPD_DAC Power on DAC1. Usually, PDAC1 needs to be tristated if we power on the DAC, i.e. IE=0, OE=0, RDE=0, RUE=0. (R/W)

RTCIO_PAD_PDAC1_MUX_SEL 0: route pad to the digital IO_MUX; (R/W)
1: route to the RTC block.

RTCIO_PAD_PDAC1_FUN_SEL the functional selection signal of the pad. (R/W)

RTCIO_PAD_PDAC1_SLP_SEL Sleep mode selection signal of the pad. Set this bit to 1 to put the pad to sleep. (R/W)

RTCIO_PAD_PDAC1_SLP_IE Input enable of the pad in sleep mode. 1: enabled; 0: disabled. (R/W)

RTCIO_PAD_PDAC1_SLP_OE Output enable of the pad. 1: enabled ; 0: disabled. (R/W)

RTCIO_PAD_PDAC1_FUN_IE Input enable of the pad. 1: enabled it; 0: disabled. (R/W)

RTCIO_PAD_PDAC1_DAC_XPD_FORCE Power on DAC1. Usually, we need to tristate PDAC1 if we power on the DAC, i.e. IE=0, OE=0, RDE=0, RUE=0. (R/W)

RTCIO_EXT_WAKEUP0_SEL		(reserved)	
31	27	53	27
0	0	0	0

RTCIO_EXT_WAKEUP0_SEL GPIO[0-17] can be used to wake up the chip when the chip is in the sleep mode. This register prompts the pad source to wake up the chip when the latter is in deep/light sleep mode. 0: select GPIO0; 1: select GPIO2, etc. (R/W)

Register 4.55: RTCIO_XTL_EXT_CTR_REG (0x0030)

RTCIO_XTL_EXT_CTR_SEL Select the external crystal power down enable source to get into sleep mode. 0: select GPIO0; 1: select GPIO2, etc. The input value on this pin XOR RTCIO_RTC_EXT_XTAL_CONF_REG[30] is the crystal power down enable signal. (R/W)

Register 4.56: RTCIO_SAR_I2C_IO_REG (0x0031)

RTCIO_SAR_I2C_SDA_SEL Selects a different pad as the RTC I2C SDA signal. 0: use pad TOUCH_PAD[1]; 1: use pad TOUCH_PAD[3]. (R/W)

RTCIO_SAR_I2C_SCL_SEL Selects a different pad as the RTC I2C SCL signal. 0: use pad TOUCH_PAD[1]; 1: use pad TOUCH_PAD[3]. (R/W)

5. SPI

5.1 Overview

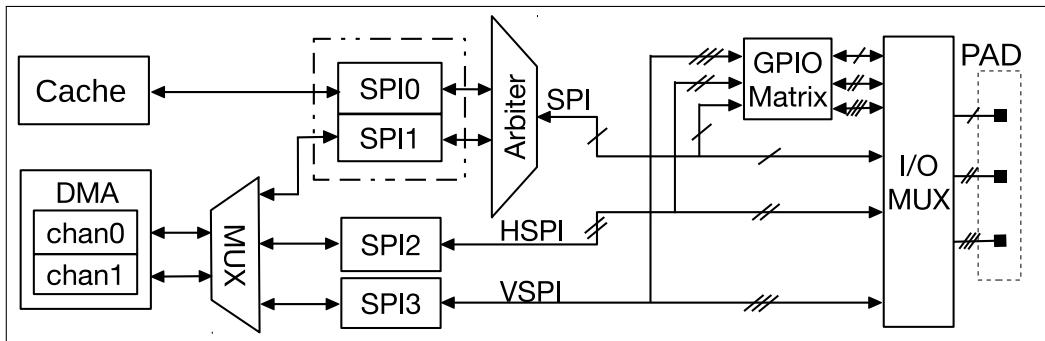

Figure 10: SPI Architecture

As Figure 10 shows, ESP32 integrates four SPI controllers which can be used to communicate with external devices that use the SPI protocol. Controller SPI0 is used as a buffer for accessing external memory. Controller SPI1 can be used as a master. Controllers SPI2 and SPI3 can be configured as either a master or a slave. When used as a master, each SPI controller can drive multiple CS signals (CS0 ~ CS2) to activate multiple slaves. Controllers SPI1 ~ SPI3 share two DMA channels.

The SPI signal buses consist of D, Q, CS0-CS2, CLK, WP, and HD signals, as Table 22 shows. Controllers SPI0 and SPI1 share one signal bus through an arbiter; the signals of the shared bus start with "SPI". Controllers SPI2 and SPI3 use signal buses starting with "HSPI" and "VSPI" respectively. The I/O lines included in the above-mentioned signal buses can be mapped to pins via either the IO_MUX module or the GPIO matrix. (Please refer to Chapter [IO_MUX](#) for details.)

The SPI controller supports four-line half-duplex and full-duplex communication (MOSI, MISO, CS, and CLK lines) and three-line-bit half-duplex-only communication (DATA, CS, and CLK lines) in GP-SPI mode. In QSPI mode, a SPI controller accesses the flash or SRAM by using signal buses D, Q, CS0 ~ CS2, CLK, WP, and HD as a four-bit parallel SPI bus. The mapping between the GP-SPI signal bus and the QSPI signal bus is shown in Table 22.

Table 22: SPI Signal and Pin Signal Function Mapping

Four-line GP-SPI Full-duplex signal bus	Three-line GP-SPI Half-duplex signal bus	QSPI Signal bus	Pin function signals		
			SPI signal bus	HSPI signal bus	VSPI signal bus
MOSI	DATA	D	SPIID	HSPID	VSPID
MISO	-	Q	SPIQ	HSPIQ	VSPIQ
CS	CS	CS	SPICS0	HSPICS0	VSPICS0
CLK	CLK	CLK	SPICLK	HSPICLK	VSPICLK
-	-	WP	SPIWP	HSPIWP	VSPIWP
-	-	HD	SPIHD	HSPIHD	VSPIHD

5.2 SPI Features

General Purpose SPI (GP-SPI)

- Programmable data transaction length, in multiples of 1 byte
- Four-line full-duplex communication and three-line half-duplex communication support
- Master mode and slave mode
- Programmable CPOL and CPHA
- Programmable clock

Parallel QSPI

- Communication format support for specific slave devices such as flash
- Programmable communication format
- Six variations of flash-read operations available
- Automatic shift between flash and SRAM access
- Automatic wait states for flash access

SPI DMA Support

- Support for sending and receiving data using linked lists

SPI Interrupt Hardware

- SPI interrupts
- SPI DMA interrupts

5.3 GP-SPI

The SPI1 ~ SPI3 controllers can communicate with other slaves as a standard SPI master. Every SPI master can be connected to three slaves at most by default. In non-DMA mode, the maximum length of data received/sent in one burst is 64 bytes. The data length is in multiples of 1 byte.

5.3.1 GP-SPI Master Mode

The SPI master mode supports four-line full-duplex communication and three-line half-duplex communication. The connections needed for four-line full-duplex communications are outlined in Figure 11.

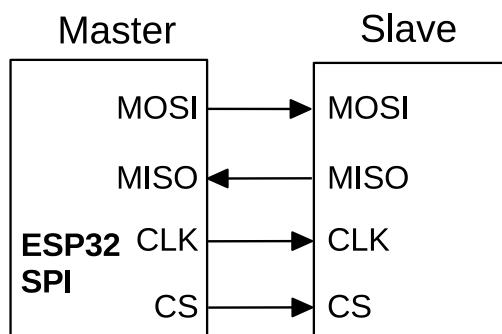

Figure 11: SPI Master and Slave Full-duplex Communication

For four-line full-duplex communication, the length of received and sent data needs to be set by configuring the SPI_MISO_DLEN_REG, SPI_MOSI_DLEN_REG registers for master mode as well as

SPI_SLV_RDBUF_DLEN_REG, SPI_SLV_WRBUF_DLEN_REG registers for slave mode. The SPI_DOUTDIN bit and SPI_USR_MOSI bit in register SPI_USER_REG should also be configured. The SPI_USR bit in register SPI_CMD_REG needs to be configured to initialize data transfer.

If ESP32 SPI is configured as a slave using three-line half-duplex communication, the master-slave communication should meet a certain communication format. Please refer to [5.3.2.1](#) for details. For example, if ESP32 SPI acts as a slave, the communication format should be: command + address + received/sent data. The address length of the master should be the same as that of the slave; the value of the address should be 0.

The byte order in which ESP32 SPI reads and writes is controlled by the SPI_RD_BYTE_ORDER bit and the SPI_WR_BYTE_ORDER bit in register SPI_USER_REG. The bit order is controlled by the SPI_RD_BIT_ORDER bit and the SPI_WR_BIT_ORDER bit in register SPI_CTRL_REG.

5.3.2 GP-SPI Slave Mode

ESP32 SPI2 ~ SPI3 can communicate with other host devices as a slave device. ESP32 SPI should use particular protocols when acting as a slave. Data received or sent at one time can be no more than 64 bytes when not using DMA. During a valid read/write process, the appropriate CS signal must be maintained at a low level. If the CS signal is pulled up during transmission, the internal state of the slave will be reset.

5.3.2.1 Communication Format Supported by GP-SPI Slave

The communication format of ESP32 SPI is: command + address + read/write data. When using half-duplex communication, the slave read and write operations use fixed hardware commands from which the address part can not be removed. The command is specified as follows:

1. command: length: 3 ~ 16 bits; Master Out Slave In (MOSI).
2. address: length: 1 ~ 32 bits; Master Out Slave In (MOSI).
3. data read/write: length 0 ~ 512 bits (64 bytes); Master Out Slave In (MOSI) or Master In Slave Out (MISO).

When ESP32 SPI is used as a slave in full-duplex communication, data transaction can be directly initiated without the master sending command and address.

5.3.2.2 Command Definitions Supported by GP-SPI Slave in Half-duplex Mode

The minimum length of a command received by the slave should be three bits. The lowest three bits correspond to fixed hardware read and write operations as follows:

1. 0x1 (received by slave): Writes data sent by the master into the slave status register via MOSI.
2. 0x2 (received by slave): Writes data sent by the master into the slave data buffer.
3. 0x3 (sent by slave): Sends data in the slave buffer to master via MISO.
4. 0x4 (sent by slave): Sends data in the slave status register to master via MISO.
5. 0x6 (received and then sent by slave): Writes master data on MOSI into data buffer and then sends the date in the slave data buffer to MISO.

The master can write the slave status register SPI_SLV_WR_STATUS_REG, and decide whether to read data from register SPI_SLV_WR_STATUS_REG or register SPI_RD_STATUS_REG via the SPI_SLV_STATUS_READBACK

bit in the register SPI_SLAVE1_REG. The SPI master can maintain communication with the slave by reading and writing slave status register, thus realizing relatively complex communication with ease.

5.3.3 GP-SPI Data Buffer

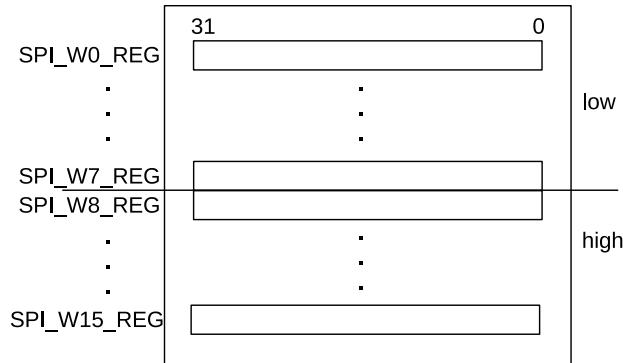

Figure 12: SPI Data Buffer

ESP32 SPI has 16×32 bits of data buffer to buffer data-send and data-receive operations. As is shown in Figure 12, received data is written from the low byte of SPI_W0_REG by default and the writing ends with SPI_W15_REG. If the data length is over 64 bytes, the extra part will be written from SPI_W0_REG.

Data buffer blocks SPI_W0_REG ~ SPI_W7_REG and SPI_W8_REG ~ SPI_W15_REG data correspond to the lower part and the higher part respectively. They can be used separately, and are controlled by the SPI_USR_MOSI_HIGHPART bit and the SPI_USR_MISO_HIGHPART bit in register SPI_USER_REG. For example, if SPI is configured as a master, when SPI_USR_MOSI_HIGHPART = 1, SPI_W8_REG ~ SPI_W15_REG are used as buffer for sending data; when SPI_USR_MISO_HIGHPART = 1, SPI_W8_REG ~ SPI_W15_REG are used as buffer for receiving data. If SPI acts as a slave, when SPI_USR_MOSI_HIGHPART = 1, SPI_W8_REG ~ SPI_W15_REG are used as buffer for receiving data; when SPI_USR_MISO_HIGHPART = 1, SPI_W8_REG ~ SPI_W15_REG are used as buffer for sending data.

5.4 GP-SPI Clock Control

The maximum output clock frequency of ESP32 GP-SPI master is $f_{\text{apb}}/2$, and the maximum input clock frequency of the ESP32 GP-SPI slave is $f_{\text{apb}}/8$. The master can derive other clock frequencies via frequency division.

$$f_{\text{spi}} = \frac{f_{\text{apb}}}{(\text{SPI_CLKCNT_N}+1)(\text{SPI_CLKDIV_PRE}+1)}$$

SPI_CLKCNT_N and SPI_CLKDIV_PRE are two bits of register SPI_CLOCK_REG (Please refer to 5.8 Register Description for details). When the SPI_CLK_EQU_SYSCLK bit in the register SPI_CLOCK_REG is set to 1, and the other bits are set to 0, SPI output clock frequency is f_{apb} . For other clock frequencies, SPI_CLK_EQU_SYSCLK needs to be 0.

5.4.1 GP-SPI Clock Polarity (CPOL) and Clock Phase (CPHA)

The clock polarity and clock phase of ESP32 SPI are controlled by the SPI_CK_IDLE_EDGE bit in register SPI_PIN_REG, the SPI_CK_OUT_EDGE bit and the SPI_CK_I_EDGE bit in register SPI_USER_REG, the SPI_MISO_DELAY_MODE[1:0] bit, the SPI_MISO_DELAY_NUM[2:0] bit, the SPI_MOSI_DELAY_MODE[1:0] bit, and the SPI_MOSI_DELAY_NUM[2:0] bit in register SPI_CTRL2_REG. Table 23 and Table 24 show the clock polarity and phase as well as the corresponding register values for ESP32 SPI master and slave, respectively.

Table 23: Clock Polarity and Phase, and Corresponding SPI Register Values for SPI Master

Registers	mode0	mode1	mode2	mode3
SPI_CK_IDLE_EDGE	0	0	1	1
SPI_CK_OUT_EDGE	0	1	1	0
SPI_MISO_DELAY_MODE	2(0)	1(0)	1(0)	2(0)
SPI_MISO_DELAY_NUM	0	0	0	0
SPI_MOSI_DELAY_MODE	0	0	0	0
SPI_MOSI_DELAY_NUM	0	0	0	0

Table 24: Clock Polarity and Phase, and Corresponding SPI Register Values for SPI Slave

Registers	mode0	mode1	mode2	mode3
SPI_CK_IDLE_EDGE	0	0	1	1
SPI_CK_I_EDGE	0	1	1	0
SPI_MISO_DELAY_MODE	0	0	0	0
SPI_MISO_DELAY_NUM	0	0	0	0
SPI_MOSI_DELAY_MODE	2	1	1	2
SPI_MOSI_DELAY_NUM	0	0	0	0

1. mode0 means CPOL=0, CPHA=0. When SPI is idle, the clock output is logic low; data change on the falling edge of the SPI clock and are sampled on the rising edge;
2. mode1 means CPOL=0, CPHA=1. When SPI is idle, the clock output is logic low; data change on the rising edge of the SPI clock and are sampled on the falling edge;
3. mode2 means when CPOL=1, CPHA=0. When SPI is idle, the clock output is logic high; data change on the rising edge of the SPI clock and are sampled on the falling edge;
4. mode3 means when CPOL=1, CPHA=1. When SPI is idle, the clock output is logic high; data change on the falling edge of the SPI clock and are sampled on the rising edge.

5.4.2 GP-SPI Timing

The data signals of ESP32 GP-SPI can be mapped to physical pins via IO_MUX or via IO_MUX and GPIO matrix. When signals pass through the matrix, they will be delayed by two clk_{apb} clock cycles.

When GP-SPI is used as master and the data signals are not received by the SPI controller via GPIO matrix, if GP-SPI output clock frequency is not higher than $clk_{apb}/2$, register SPI_MISO_DELAY_MODE should be set to 0 when configuring the clock polarity. If GP-SPI output clock frequency is not higher than $clk_{apb}/4$, register

SPI_MISO_DELAY_MODE can be set to the corresponding value in Table 23 when configuring the clock polarity.

When GP-SPI is used in master mode and the data signals enter the SPI controller via the GPIO matrix:

1. If GP-SPI output clock frequency is $clk_{apb}/2$, register SPI_MISO_DELAY_MODE should be set to 0 and the dummy state should be enabled (SPI_USR_DUMMY = 1) for one clk_{spi} clock cycle (SPI_USR_DUMMY_CYCLELEN = 0) when configuring the clock polarity;
2. If GP-SPI output clock frequency is $clk_{apb}/4$, register SPI_MISO_DELAY_MODE should be set to 0 when configuring the clock polarity;
3. If GP-SPI output clock frequency is not higher than $clk_{apb}/8$, register SPI_MISO_DELAY_MODE can be set to the corresponding value in Table 23 when configuring the clock polarity.

When GP-SPI is used in slave mode, the maximum slave input clock frequency is $f_{apb}/8$. In addition, the clock signal and the data signals should be routed to the SPI controller via the same path, i.e., neither the clock signal nor the data signals enter the SPI controller via the GPIO matrix, or both the clock signal and the data signals enter the SPI controller via the GPIO matrix. This is important in ensuring that the signals are not delayed by different time periods before they reach the SPI hardware.

5.5 Parallel QSPI

ESP32 SPI controllers support SPI bus memory devices (such as flash and SRAM). The hardware connection between the SPI pins and the memories is shown by Figure 13.

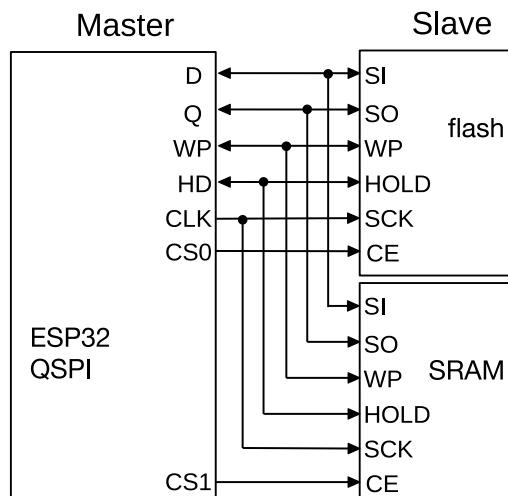

Figure 13: Parallel QSPI

SPI1, SPI2 and SPI3 controllers can also be configured as QSPI master to connect to external memory. The maximum output clock frequency of the SPI memory interface is f_{apb} , with the same clock configuration as that of the GP-SPI master.

ESP32 QSPI supports flash-read operation in one-line mode, two-line mode, and four-line mode.

5.5.1 Communication Format of Parallel QSPI

To support communication with special slave devices, ESP32 QSPI implements a specifically designed communication protocol. The communication format of ESP32 QSPI master is command + address + read/write data, as shown in Figure 14, with details as follows:

1. Command: length: 1 ~ 16 bits; Master Out Slave In.
2. Address: length: 0 ~ 64 bits; Master Out Slave In.
3. Data read/write: length: 0 ~ 512 bits (64 bytes); Master Out Slave In or Master In Slave Out.

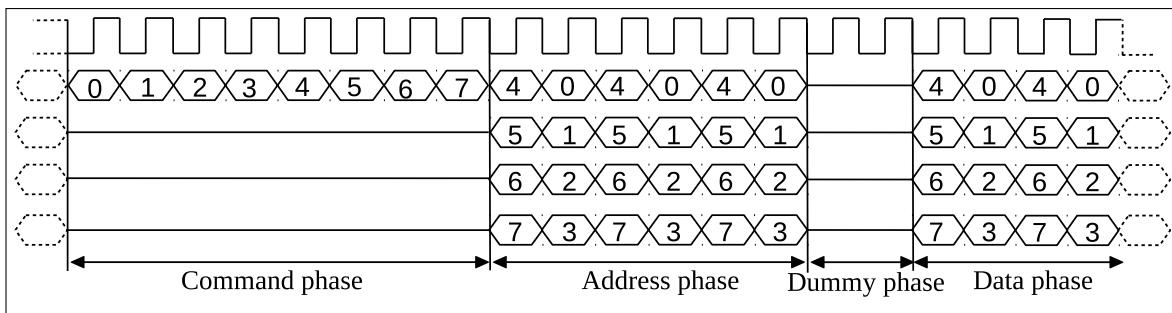

Figure 14: Communication Format of Parallel QSPI

When ESP32 SPI is configured as a master and communicates with slaves that use the SPI protocol, options such as command, address, data, etc., can be adjusted as required by the specific application. When ESP32 SPI reads special devices such as Flash and SRAM, a dummy state with a programmable length can be inserted between the address phase and the data phase.

5.6 GP-SPI Interrupt Hardware

ESP32 SPI generates two types of interrupts. One is the SPI interrupt and the other is the SPI DMA interrupt.

ESP32 SPI reckons the completion of send and/or receive operations as the completion of one operation from the controller and generates one interrupt. When ESP32 SPI is configured to slave mode, the slave will generate read/write status registers and read/write buffer data interrupts according to different operations.

5.6.1 SPI Interrupts

The SPI_*_INTEN bits in the SPI_SLAVE_REG register can be set to enable SPI interrupts. When an SPI interrupt happens, the interrupt flag in the corresponding SPI_*_DONE register will get set. This flag is writable, and an interrupt can be cleared by setting the bit to zero.

- SPI_TRANS_DONE_INT: Triggered when a SPI operation is done.
- SPI_SLV_WR_STA_INT: Triggered when a SPI slave status write is done.
- SPI_SLV_RD_STA_INT: Triggered when a SPI slave status read is done.
- SPI_SLV_WR_BUF_INT: Triggered when a SPI slave buffer write is done.
- SPI_SLV_RD_BUF_INT: Triggered when a SPI slave buffer read is done.

5.6.2 DMA Interrupts

- SPI_OUT_TOTAL_EOF_INT: Triggered when all linked lists are sent.
- SPI_OUT_EOF_INT: Triggered when one linked list is sent.
- SPI_OUT_DONE_INT: Triggered when the last linked list item has zero length.
- SPI_IN_SUC_EOF_INT: Triggered when all linked lists are received.
- SPI_IN_ERR_EOF_INT: Triggered when there is an error receiving linked lists.
- SPI_IN_DONE_INT: Triggered when the last received linked list had a length of 0.
- SPI_INLINK_DSCR_ERROR_INT: Triggered when the received linked list is invalid.
- SPI_OUTLINK_DSCR_ERROR_INT: Triggered when the linked list to be sent is invalid.
- SPI_INLINK_DSCR_EMPTY_INT: Triggered when no valid linked list is available.

0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	Reset		

SPI_USR This bit is used to enable user-defined commands. An operation will be triggered when this bit is set. The bit will be cleared once the operation is done. (R/W)

Register 5.2: SPI_ADDR_REG (0x4)

31	0
0x0000000000	Reset

SPI_ADDR_REG Address to slave or from master. If the address length is bigger than 32 bits, SPI_SLV_WR_STATUS_REG contains the lower 32 bits while this register contains the higher address bits. (R/W)

Register 5.3: SPI_CTRL_REG (0x8)

SPI_WR_BIT_ORDER This bit determines the bit order for command, address and MOSI data writes.

1: sends LSB first; 0: sends MSB first. (R/W)

SPI_RD_BIT_ORDER This bit determines the bit order for MOSI data reads. 1: receives LSB first; 0: receives MSB first. (R/W)

SPI_FREAD_QIO This bit determines whether to use four data lines for address writes and MOSI data reads or not. 1: enable; 0: disable. (R/W)

SPI_FREAD_DIO This bit determines whether to use two data lines for address writes and MOSI data reads or not. 1: enable; 0: disable. (R/W)

SPI_WP This bit determines the write-protection signal output when SPI is idle. 1: output high; 0: output low. (R/W)

SPI_FREAD_QUAD This bit determines whether to use four data lines for MOSI data reads or not. 1: enable; 0: disable. (R/W)

SPI_FREAD_DUAL This bit determines whether to use two data lines for MOSI data reads or not. 1: enable; 0: disable. (R/W)

SPI_FASTRD_MODE This bit is used to enable spi_fread_qio, spi_fread_dio, spi_fread_qout, and spi_fread_dout. 1: enable 0: disable. (R/W)

Register 5.4: SPI_CTRL1_REG (0xC)

SPI_CS_DELAY_NUM The spi_cs signal is delayed by the number of system clock cycles configured here. (R/W)

SPI_CS_DELAY_MODE This register field determines the way the spi_cs signal is delayed by spi_clk. (R/W)

0: none.

1: if SPI_CK_OUT_EDGE or SPI_CK_I_EDGE is set, spi_cs is delayed by half a cycle, otherwise it is delayed by one cycle.

2: if SPI_CK_OUT_EDGE or SPI_CK_I_EDGE is set, spi_cs is delayed by one cycle, otherwise it is delayed by half a cycle.

3: the spi_cs signal is delayed by one cycle.

SPI_MOSI_DELAY_NUM The MOSI signals are delayed by the number of system clock cycles configured here. (R/W)

SPI_MOSI_DELAY_MODE This register field determines the way the MOSI signals are delayed by spi_clk. (R/W)

0: none.

1: if SPI_CK_OUT_EDGE or SPI_CK_I_EDGE is set, the MOSI signals are delayed by half a cycle, otherwise they are delayed by one cycle.

2: if SPI_CK_OUT_EDGE or SPI_CK_I_EDGE is set, the MOSI signals are delayed by one cycle, otherwise they are delayed by half a cycle.

3: the MOSI signals are delayed one cycle.

SPI_MISO_DELAY_NUM The MISO signals are delayed by the number of system clock cycles specified here. (R/W)

SPI_MISO_DELAY_MODE This register field determines the way MISO signals are delayed by spi_clk. (R/W)

0: none.

1: if SPI_CK_OUT_EDGE or SPI_CK_I_EDGE is set, the MISO signals are delayed by half a cycle, otherwise they are delayed by one cycle.

2: if SPI_CK_OUT_EDGE or SPI_CK_I_EDGE is set, the MISO signals are delayed by one cycle, otherwise they are delayed by half a cycle.

3: the MISO signals are delayed by one cycle.

SPI_HOLD_TIME The number of spi_clk cycles by which CS pin signals are delayed. These bits are used in conjunction with the SPI_CS_HOLD bit. (R/W)

SPI_SETUP_TIME The number of spi_clk cycles for which spi_cs is made active before the SPI data transaction starts. This register field is used when SPI_CS_SETUP is set. (R/W)

Register 5.7: SPI_CLOCK_REG (0x18)

The diagram shows the bit field layout of the SPI_CLOCK_REG register. It consists of a 32-bit register divided into four main sections: SPI_CLK_EQU_SYSCLK (bits 31-30), SPI_CLKDIV_PRE (bits 18-17), SPI_CLKCNT_N (bits 12-11), SPI_CLKCNT_H (bit 6), SPI_CLKCNT_L (bit 5), and a Reset bit (bit 0). The SPI_CLK_EQU_SYSCLK section is labeled with an upward arrow. The SPI_CLKDIV_PRE section is labeled with a downward arrow. The SPI_CLKCNT_N section is labeled with an upward arrow. The SPI_CLKCNT_H section is labeled with a downward arrow. The SPI_CLKCNT_L section is labeled with an upward arrow. The Reset bit is labeled "Reset".

31	30	18	17	12	11	6	5	0
1	0	0	0	0	0	0x03	0x01	0x03

SPI_CLK_EQU_SYSCLK In master mode, when this bit is set to 1, spi_clk is equal to system clock; when set to 0, spi_clk is divided from system clock. (R/W)

SPI_CLKDIV_PRE In master mode, the value of this register field is the pre-divider value for spi_clk, minus one. (R/W)

SPI_CLKCNT_N In master mode, this is the divider for spi_clk minus one. The spi_clk frequency is $\text{system_clock}/(\text{SPI_CLKDIV_PRE}+1)/(\text{SPI_CLKCNT_N}+1)$. (R/W)

SPI_CLKCNT_H For a 50% duty cycle, set this to $\text{floor}((\text{SPI_CLKCNT_N}+1)/2-1)$. (R/W)

SPI_CLKCNT_L In master mode, this must be equal to SPI_CLKCNT_N. In slave mode this must be 0. (R/W)

Register 5.8: SPI_USER_REG (0x1C)

SPI_USR_COMMAND	SPI_USR_ADDR	SPI_USR_DUMMY	SPI_USR_MOSI	SPI_USR_DUMMY_IDLE	SPI_USR_MOSI_HIGHPART	(reserved)	SPI_SIO	SPI_FWRITE_QIO	SPI_FWRITE_DIO	SPI_FWRITE_QUAD	SPI_WR_BYTE_ORDER	SPI_RD_BYTE_ORDER	(reserved)	SPI_CK_OUT_EDGE	SPI_CK_IN_EDGE	SPI_CS_SETUP	SPI_CS_HOLD	(reserved)	SPI_DOUTDIN

1	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1	0	0	0	0	0	Reset

SPI_USR_COMMAND This bit enables the command phase of an operation. (R/W)

SPI_USR_ADDR This bit enables the address phase of an operation. (R/W)

SPI_USR_DUMMY This bit enables the dummy phase of an operation. (R/W)

SPI_USR_MISO This bit enables the read-data phase of an operation. (R/W)

SPI_USR_MOSI This bit enables the write-data phase of an operation. (R/W)

SPI_USR_DUMMY_IDLE The spi_clk signal is disabled in the dummy phase when the bit is set. (R/W)

SPI_USR_MOSI_HIGHPART If set, data written to the device is only read from SPI_W8-SPI_W15 of the SPI buffer. (R/W)

SPI_USR_MISO_HIGHPART If set, data read from the device is only written to SPI_W8-SPI_W15 of the SPI buffer. (R/W)

SPI_SIO Set this bit to enable three-line half-duplex communication where MOSI and MISO signals share the same pin. (R/W)

SPI_FWRITE_QIO This bit enables the use of four data lines for address and MISO data writes. 1: enable; 0: disable. (R/W)

SPI_FWRITE_DIO This bit enables the use of two data lines for address and MISO data writes. 1: enable; 0: disable. (R/W)

SPI_FWRITE_QUAD This bit enables the use of four data lines for MISO data writes. 1: enable; 0: disable. (R/W)

SPI_FWRITE_DUAL This bit determines whether to use two data lines for MISO data writes or not. 1: enable; 0: disable. (R/W)

SPI_WR_BYTE_ORDER This bit determines the byte-endianness for writing command, address, and MOSI data. 1: big-endian; 0: little-endian. (R/W)

SPI_RD_BYTE_ORDER This bit determines the byte-endianness for reading MISO data. 1: big-endian; 0: little_endian. (R/W)

SPI_CK_OUT_EDGE This bit, combined with SPI_MOSI_DELAY_MODE, sets the MOSI signal delay mode. (R/W)

SPI_CK_I_EDGE In slave mode, the bit is the same as SPI_CK_OUT_EDGE in master mode. It is combined with SPI_MISO_DELAY_MODE. (R/W)

SPI_CS_SETUP Setting this bit enables a delay between spi_cs being active and starting data transfer, as specified in SPI_SETUP_TIME. This bit only is valid in half-duplex mode, that is, when SPI_DOUTDIN is not set. (R/W)

SPI_CS_HOLD Setting this bit enables a delay between the end of a transmission and spi_cs being made inactive, as specified in SPI_HOLD_TIME. (R/W)

SPI_DOUTDIN Set the bit to enable full-duplex communication, meaning that MOSI data is sent out at the same time MISO data is received. 1: enable; 0: disable. (R/W)

Register 5.9: SPI_USER1_REG (0x20)

31	26	25		8	7	0
23	0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0			7		Reset

SPI_USR_ADDR_BITLEN The bit length of the address phase minus one. (RO)

SPI_USR_DUMMY_CYCLELEN The number of spi_clk cycles for the dummy phase, minus one. (R/W)

Register 5.10: SPI_USER2_REG (0x24)

SPI_USR_COMMAND_BITLEN The bit length of the command phase minus one. (R/W)

SPI_USR_COMMAND_VALUE The value of the command. (R/W)

Register 5.11: SPI_MOSI_DLEN_REG (0x28)

31	24	23	0
0 0 0 0 0 0 0 0 0		0x00000000	Reset

SPI_USR_MOSI_DBITLEN The bit length of the data to be written to the device minus one. (R/W)

Register 5.12: SPI_MISO_DLEN_REG (0x2C)

(reserved)	SPIUSR_MISO_DBITLEN	Reset
31 0 0 0 0 0 0 0 0	24 0x0000000	23 0 Reset

SPIUSR_MISO_DBITLEN The bit length of the data to be read from the device, minus one. (R/W)

Register 5.13: SPI_SLV_WR_STATUS_REG (0x30)

SPI_SLV_WR_STATUS_REG	Reset
31 0	0

SPI_SLV_WR_STATUS_REG In the slave mode this register is the status register for the master to write into. In the master mode, if the address length is bigger than 32 bits, this register contains the lower 32 bits. (R/W)

Register 5.14: SPI_PIN_REG (0x34)

(reserved)	SPI_CS_KEEP_ACTIVE	(reserved)	SPI_MASTER_CK_SEL	(reserved)	SPI_MASTER_CS_POL	(reserved)	SPI_CS2_DIS	(reserved)	SPI_CS1_DIS	(reserved)	SPI_CS0_DIS

0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1	1	0

SPI_CS_KEEP_ACTIVE When set, the spi_cs will be kept active even when not in a data transaction.
(R/W)

SPI_CK_IDLE_EDGE The idle state of the spi_clk line. (R/W)

- 1: the spi_clk line is high when idle;
- 0: the spi_clk line is low when idle.

SPI_MASTER_CK_SEL This register field contains one bit per spi_cs line. When a bit is set in master mode, the corresponding spi_cs line is made active and the spi_cs pin outputs spi_clk. (R/W)

SPI_MASTER_CS_POL This register filed selects the polarity of the spi_cs line. It contains one bit per spi_cs line. Possible values of the bits: (R/W)

- 0: spi_cs is active-low;
- 1: spi_cs is active-high.

SPI_CK_DIS When set, output of the spi_clk signal is disabled. (R/W)

SPI_CS2_DIS This bit enables the SPI CS2 pin. 1: disables CS2; 0: spi_cs2 is active during the data transaction. (R/W)

SPI_CS1_DIS This bit enables the SPI CS1 pin. 1: disables CS1; 0: spi_cs1 is active during the data transaction (R/W)

SPI_CS0_DIS This bit enables the SPI CS0 pin. 1: disables CS0; 0: spi_cs0 is active during the data transaction. (R/W)

Register 5.15: SPI_SLAVE_REG (0x38)

SPI_SYNC_RESET	SPI_SLAVE_MODE	SPI_SLV_WR_RD_BUF_EN	SPI_SLV_CMD_DEFINE	SPI_TRANS_CNT	SPI_SLV_LAST_STATE	SPI_SLV_LAST_COMMAND	(reserved)	SPI_CS_I_MODE	SPI_TRANS_INTEN	SPI_SLV_WR_STA_INTEN	SPI_SLV_RD_STA_INTEN	SPI_SLV_WP_BUF_INTEN	SPI_SLV_RD_BUF_INTEN	SPI_TRANS_DONE	SPI_SLV_WR_STA_DONE	SPI_SLV_RD_STA_DONE	SPI_SLV_WP_BUF_DONE	SPI_SLV_RD_BUF_DONE

0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	Reset	

SPI_SYNC_RESET This bit is used to enable software reset. When set, it resets the latched values of the SPI clock line, cs line and data lines. (R/W)

SPI_SLAVE_MODE This bit is used to set the mode of the SPI device. (R/W)

1: slave mode;

0: master mode.

SPI_SLV_WR_RD_BUF_EN Setting this bit enables the write and read buffer commands in slave mode. (R/W)

SPI_SLV_WR_RD_STA_EN Setting this bit enables the write and read status commands in slave mode. (R/W)

SPI_SLV_CMD_DEFINE This bit is used to enable custom slave mode commands. (R/W)

1: slave mode commands are defined in SPI_SLAVE3.

0: slave mode commands are fixed as: 0x1: write-status; 0x2: write-buffer, 0x3: read-buffer; and 0x4: read-status.

SPI_TRANS_CNT The counter for operations in both the master mode and the slave mode. (RO)

SPI_SLV_LAST_STATE In slave mode, this contains the state of the SPI state machine. (RO)

SPI_SLV_LAST_COMMAND In slave mode, this contains the value of the received command. (RO)

SPI_CS_I_MODE In the slave mode, this selects the mode to synchronize the input SPI cs signal and eliminate SPI cs jitter. (R/W)

0: configured through registers (SPI_CS_DELAY_NUM and SPI_CS_DELAY_MODE);

1: using double synchronization method and configured through registers (SPI_CS_DELAY_NUM and SPI_CS_DELAY_MODE);

2: using double synchronization method.

SPI_TRANS_INTEN The interrupt enable bit for the [SPI_TRANS_DONE_INT](#) interrupt. (R/W)

SPI_SLV_WR_STA_INTEN The interrupt enable bit for the [SPI_SLV_WR_STA_INT](#) interrupt. (R/W)

SPI_SLV_RD_STA_INTEN The interrupt enable bit for the [SPI_SLV_RD_STA_INT](#) interrupt. (R/W)

SPI_SLV_WP_BUF_INTEN The interrupt enable bit for the [SPI_SLV_WP_BUF_INT](#) interrupt. (R/W)

SPI_SLV_RD_BUF_INTEN The interrupt enable bit for the [SPI_SLV_RD_BUF_INT](#) interrupt. (R/W)

SPI_TRANS_DONE The raw interrupt status bit for the [SPI_TRANS_DONE_INT](#) interrupt. (R/W)

SPI_SLV_WR_STA_DONE The raw interrupt status bit for the [SPI_SLV_WR_STA_INT](#) interrupt. (R/W)

SPI_SLV_RD_STA_DONE The raw interrupt status bit for the [SPI_SLV_RD_STA_INT](#) interrupt. (R/W)

SPI_SLV_WP_BUF_DONE The raw interrupt status bit for the [SPI_SLV_WP_BUF_INT](#) interrupt. (R/W)

SPI_SLV_RD_BUF_DONE The raw interrupt status bit for the [SPI_SLV_RD_BUF_INT](#) interrupt. (R/W)

SPI_SLV_STATUS_BITLEN In slave mode, this sets the length of the status field. (R/W)

SPI_SLV_STATUS_FAST_EN In slave mode, this enables fast reads of the status. (R/W)

SPI_SLV_STATUS_READBACK In slave mode, this selects the active status register. (R/W)

- 1: reads register of SPI_SLV_WR_STATUS;
- 0: reads register of SPI_RD_STATUS.

SPI_SLV_RD_ADDR_BITLEN In slave mode, this contains the address length in bits for a read-buffer operation, minus one. (R/W)

SPI_SLV_WR_ADDR_BITLEN In slave mode, this contains the address length in bits for a write-buffer operation, minus one. (R/W)

SPI_SLV_WRSTA_DUMMY_EN In slave mode, this bit enables the dummy phase for write-status operations. (R/W)

SPI_SLV_RDSTA_DUMMY_EN In slave mode, this bit enables the dummy phase for read-status operations. (R/W)

SPI_SLV_WRBUF_DUMMY_EN In slave mode, this bit enables the dummy phase for write-buffer operations. (R/W)

SPI_SLV_RDBUF_DUMMY_EN In slave mode, this bit enables the dummy phase for read-buffer operations. (R/W)

6. I2C Controller

6.1 Overview

An I2C (Inter-Integrated Circuit) bus can be used for communication with several external devices connected to the same bus as ESP32. The ESP32 has dedicated hardware to communicate with peripherals on the I2C bus.

6.2 Features

The I2C controller has the following features:

- Supports both master mode and slave mode
- Supports multi-master and multi-slave communication
- Supports standard mode (100 kbit/s)
- Supports fast mode (400 kbit/s)
- Supports 7-bit addressing and 10-bit addressing
- Supports continuous data transmission with disabled Serial Clock Line (SCL)
- Supports programmable digital noise filter

6.3 Functional Description

6.3.1 Introduction

I2C is a two-wire bus, consisting of an SDA and an SCL line. These lines are configured to open the drain output. The lines are shared by two or more devices, usually one or more masters and one or more slaves.

Communication starts when a master sends out a start condition: it will pull the SDA line low, and will then pull the SCL line high. It will send out nine clock pulses over the SCL line. The first eight pulses are used to shift out a byte, consisting of a 7-bit address and a read/write bit. If a slave with this address is active on the bus, the slave can answer by pulling the SDA low on the ninth clock pulse. The master can now send out more 9-bit clock pulse clusters and, depending on the read/write bit sent, the device or the master will shift out data on the SDA line, with the other side acknowledging the transfer by pulling SDA low on the ninth clock pulse. During data transfer, the SDA line changes only when the SCL line is low. When the master has finished the communication, it will send a stop condition on the bus by raising SDA, while SCL will already be high.

The ESP32 I2C peripheral can handle the I2C protocol, freeing up the processor cores for other tasks.

6.3.2 Architecture

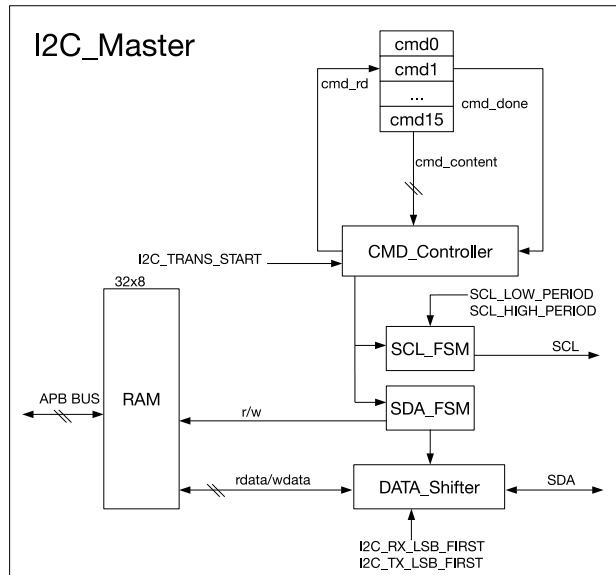

Figure 15: I2C Master Architecture

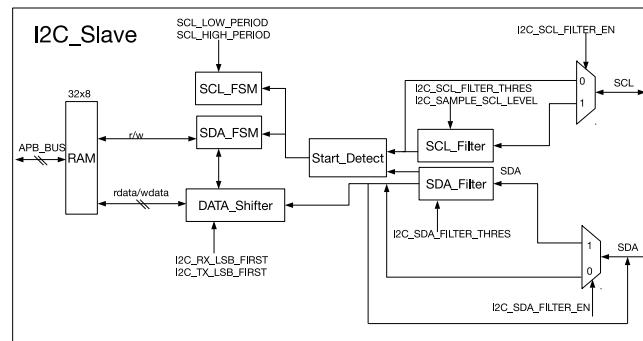

Figure 16: I2C Slave Architecture

An I2C controller can operate either in master mode or slave mode. The I2C_MS_MODE register is used to select the mode. Figure 15 shows the I2C Master architecture, while Figure 16 shows the I2C Slave architecture. The I2C controller contains the following units:

- RAM, the size of which is 32 x 8 bit and it is directly mapped onto the address space of the CPU cores, starting at address REG_I2C_BASE+0x100. Each byte of I2C data is stored in a 32-bit word of memory (so the first byte is at +0x100, the second byte at +0x104, the third byte at +0x108, etc.)
- A CMD_Controller and 16 command registers (cmd0 ~ cmd15), which are used by I2C Master to control data transmission. One command at a time is executed by the I2C controller.
- SCL_FSM: A state machine that controls the SCL clock. The I2C_SCL_HIGH_PERIOD_REG and I2C_SCL_LOW_PERIOD_REG registers are used to configure the frequency and duty cycle of the signal on the SCL line.
- SDA_FSM: A state machine that controls the SDA data line.
- DATA_Shifter which converts the byte data to an outgoing bitstream, or converts an incoming bitstream to byte data. I2C_RX_LSB_FIRST and I2C_TX_LSB_FIRST can be used for configuring whether the LSB or MSB is stored or transmitted first.

- SCL_Filter and SDA_Filter: Input noise filter for the I2C_Slave. The filter can be enabled or disabled by configuring I2C_SCL_FILTER_EN and I2C_SDA_FILTER_EN. The filter can remove line glitches with pulse width less than I2C_SCL_FILTER_THRES and I2C_SDA_FILTER_THRES ABP clock cycles.

6.3.3 I2C Bus Timing

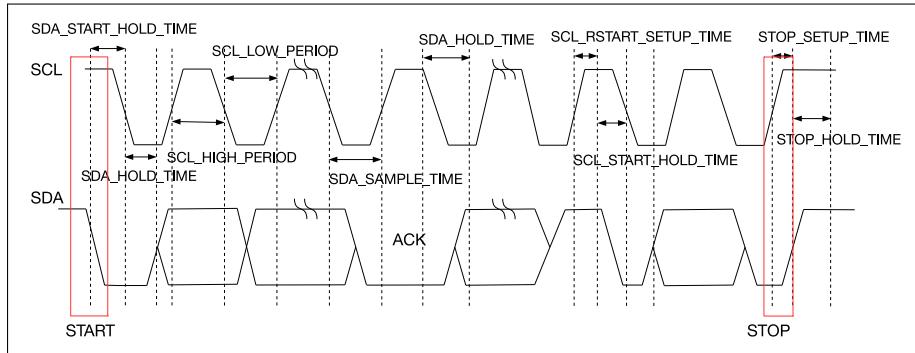

Figure 17: I2C Sequence Chart

Figure 17 is an I2C sequence chart. When the I2C controller works in master mode, SCL is an output signal. In contrast, when the I2C controller works in slave mode, SCL becomes an input signal.

According to the I2C protocol, each transmission of data begins with a START condition and ends with a STOP condition. Data is transmitted by one byte a time, and each byte has an ACK bit. The receiver informs the transmitter to continue transmission by pulling down SDA, which indicates an ACK. The receiver can also indicate it wants to stop the transmission by not pulling down the SDA line, thereby not giving an ACK.

Figure 17 also shows the registers that can configure the START bit, STOP bit, SDA hold time, and SDA sample time.

6.3.4 I2C cmd Structure

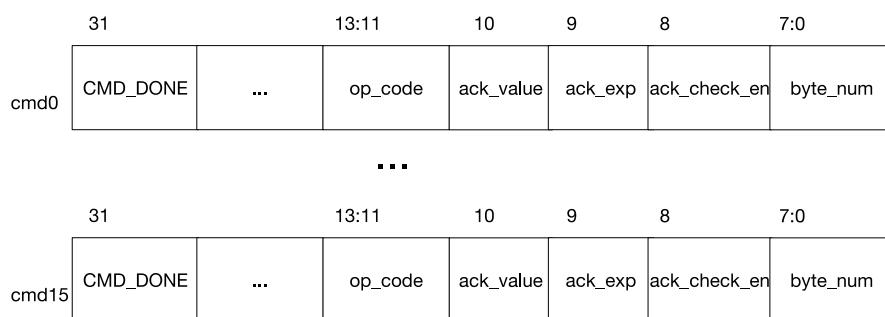

Figure 18: Structure of The I2C Command Register

The Command register is active only in I2C master mode, with its internal structure shown in Figure 18.

CMD_DONE: The CMD_DONE bit of every command can be read by software to tell if the command has been handled by hardware.

op_code: op_code is used to indicate the command. The I2C controller supports four commands:

- RSTART: op_code = 0 is the RSTART command to control the transmission of a START or RESTART I2C condition.
- WRITE: op_code = 1 is the WRITE command for the I2C Master to transmit data.

- READ: op_code = 2 is the READ command for the I2C Master to receive data.
- STOP: op_code = 3 is the STOP command to control the transmission of a STOP I2C condition.
- END: op_code = 4 is the END command for continuous data transmission. When the END command is given, SCL is temporarily disabled to allow software to reload the command and data registers for subsequent events before resuming. Transmission will then continue seamlessly.

A complete data transmission process begins with an RSTART command, and ends with a STOP command.

ack_value: When receiving data, this bit is used to indicate whether the receiver will send an ACK after this byte has been received.

ack_exp: This bit is to set an expected ACK value for the transmitter.

ack_check_en: When transmitting a byte, this bit enables checking the ACK value received against the ack_exp value. Checking is enabled by 1, while 0 disables it.

byte_num: This register specifies the length of data to be read or written. When the op_code is RSTART, STOP or END, this value has no meaning.

6.3.5 I2C Master Writes to Slave

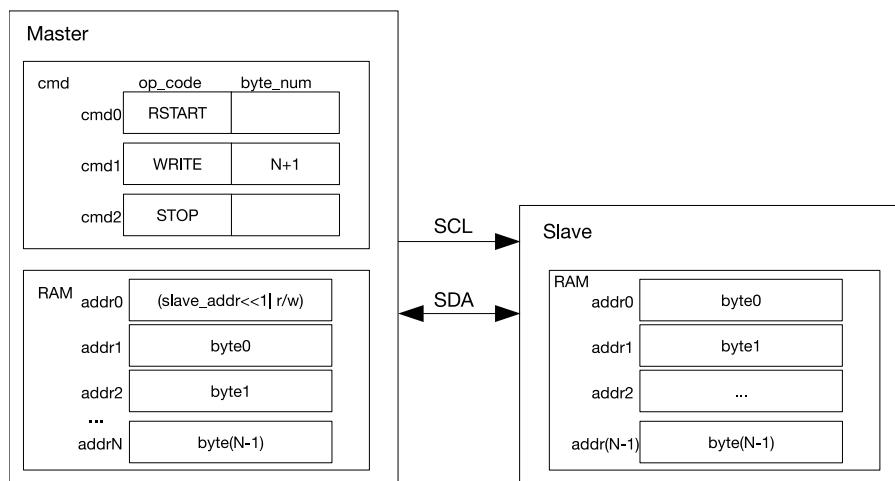

Figure 19: I2C Master Writes to Slave with 7-bit Address

Figure 19 shows the I2C Master writing N bytes of data to an external I2C Slave; both are supposed to be ESP32 I2C controllers. According to the I2C protocol, the first byte is the Slave address. As shown in the diagram, the first byte of the RAM unit has been populated with the Slave's 7-bit address plus the 1-bit read/write flag. In this case, the flag is zero, indicating a write operation. The rest of the RAM unit stores N bytes of data that are ready for transmission. The cmd unit has been populated with the sequence of commands for the operation.

The FIFO offset in RAM can be configured via the TXFIFO_START_ADDR field in the RXFIFO_ST_REG register.

When all registers are ready, the I2C_TRANS_START bit in I2C_CTR_REG is set to start the transmission. Then, the I2C Master initiates a START condition to activate the slave devices. I2C Master will then progress to the WRITE command which will cause N+1 bytes to be fetched from RAM and sent to the Slave. The first of these bytes is the address byte. Each slave device will compare this to its own. If the addresses do not match, the slave will ignore the rest of the transmission. If they do match, the slave will ACK the initial byte and the I2C master will continue sending the rest of the data; when ack_check_en is set to 'one', Master will check ACK value.

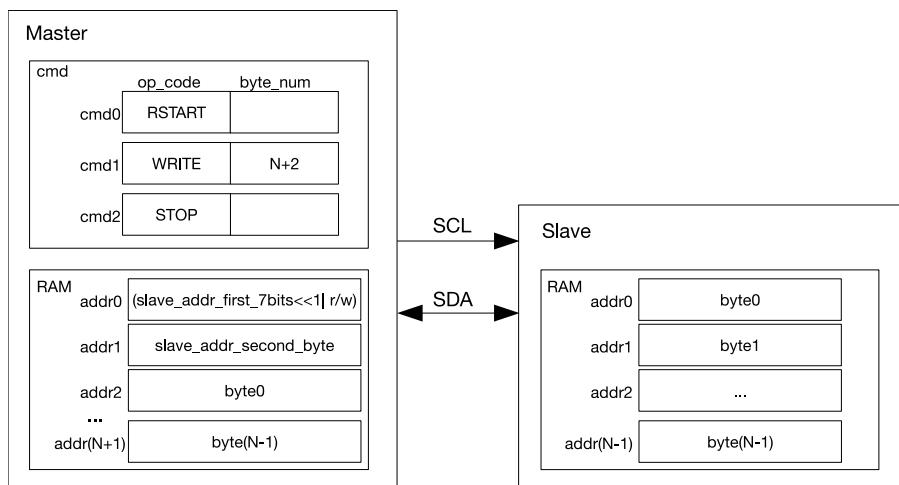

Figure 20: I2C Master Writes to Slave with 10-bit Address

The I2C controller uses 7-bit addressing by default. However, 10-bit addressing can also be used. In the master, this is done by sending a second I2C address byte after the first address byte. In the slave, the I2C_SLAVE_ADDR_10BIT_EN register bit can be set to activate a 10-bit addressing. I2C_SLAVE_ADDR is used to configure I2C Slave's address, as per usual. Figure 20 shows the equivalent of I2C Master operation writing N-bytes of data to an I2C Slave with a 10-bit address. Since 10-bit Slave addresses require an extra address byte, both the byte_num field of the WRITE command and the number of total bytes in RAM increase by one.

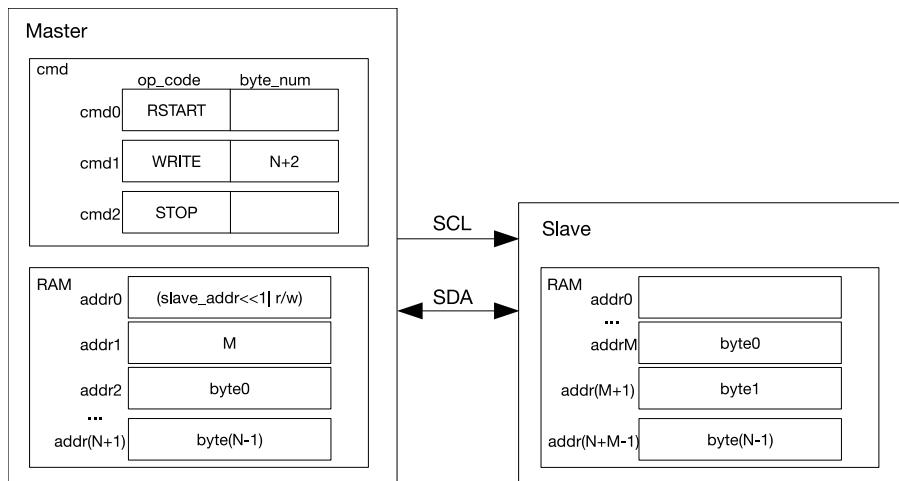

Figure 21: I2C Master Writes to addrM in RAM of Slave with 7-bit Address

One way many I2C Slave devices are designed is by exposing a register block containing various settings. The I2C Master can write one or more of these registers by sending the Slave a register address. The ESP32 I2C Slave controller has hardware support for such a scheme.

Specifically, on the Slave, I2C_FIFO_ADDR_CFG_EN can be set so that the I2C Master can write to a specified register address inside the I2C Slave memory block. Figure 21 shows the I2C Master writing N-bytes of data byte0 ~ byte(N-1) from the RAM unit to register address M (determined by addrM in RAM unit) with the Slave.

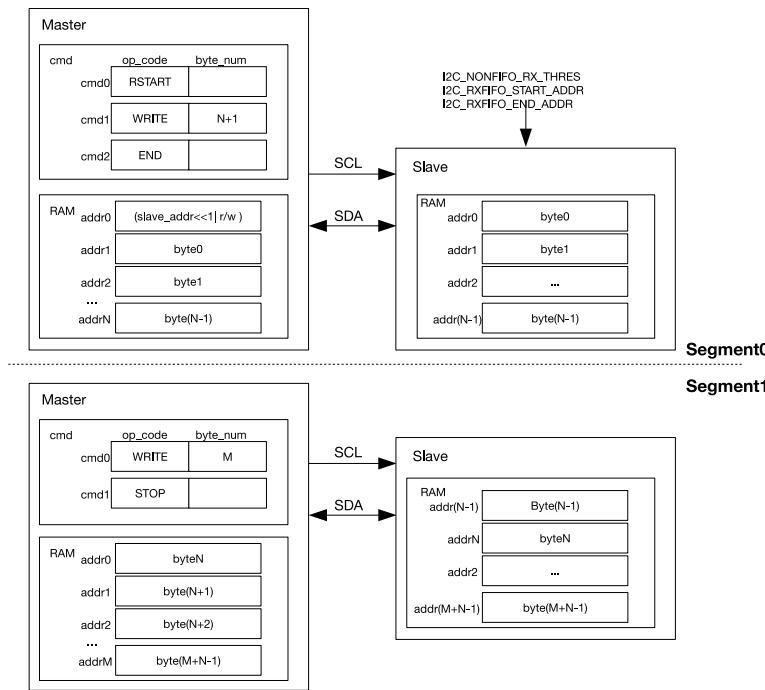

Figure 22: I2C Master Writes to Slave with 7-bit Address in Two Segments

If the data size exceeds the RAM unit capacity of 32 bytes, the END command can be called to enable segmented transmission. Figure 22 shows I2C Master writing data in two segments to Slave. The upper part of the figure shows the configuration of the first sequence of bytes in the transfer. I2C Master will turn off SCL clock, after executing the END command and after the controller generates the I2C_END_DETECT_INT interrupt.

On receiving I2C_END_DETECT_INT (or polling the CMD_DONE bit of the command register the END was placed into), software should refresh the contents of the cmd and RAM units, as shown in the lower part of the figure. Subsequently, it should clear the I2C_END_DETECT_INT interrupt and resume the transaction by setting the I2C_TRANS_START bit in CTR_CTR_REG.

6.3.6 I2C Master Reads from Slave

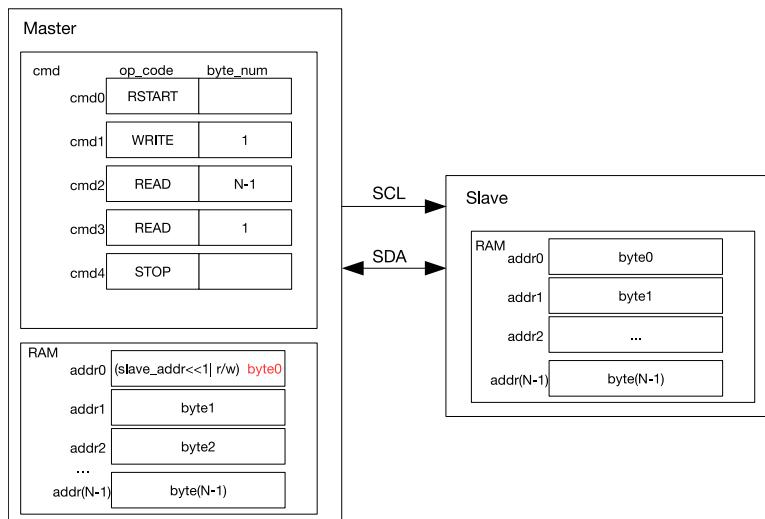

Figure 23: I2C Master Reads from Slave with 7-bit Address

Figure 23 shows the I2C Master reading N-bytes of data from an I2C Slave with a 7-bit address. At first, the I2C Master needs to send the address of the I2C Slave, so cmd1 is a WRITE command. The byte that this command

sends is the I2C slave address plus the R/W flag, which in this case is 1 and, therefore, indicates that this is going to be a read operation. According to the I2C protocol, I2C Master will not return ACK on receiving the last byte of data read from the slave; consequently, READ is divided into two segments. The I2C Master replies ACK to N-1 bytes in cmd2 and does not reply ACK to the single byte READ command in cmd3, i.e., the last transmitted data.

When storing the received data, I2C Master will start from the first address in RAM. Byte0 (Slave address + 1-bit R/W marker bit) will be overwritten. The FIFO RAM offsets reading and writing data which can then be configured via the RXFIFO_START_ADDR and TXFIFO_START_ADDR fields in the RXFIFO_ST_REG register.

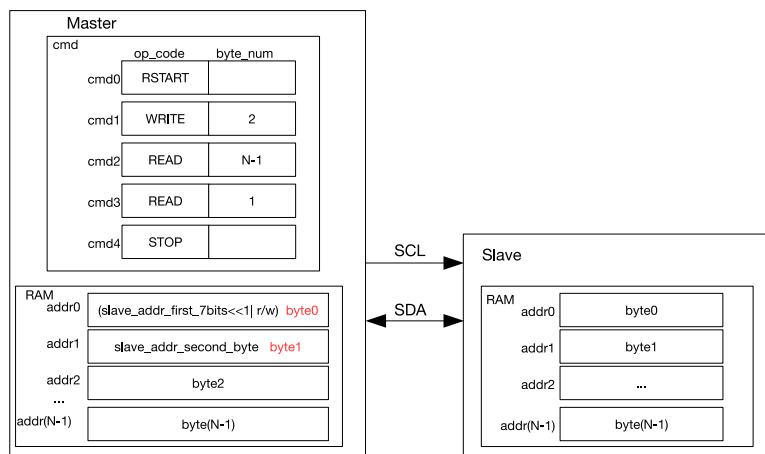

Figure 24: I2C Master Reads from Slave with 10-bit Address

Figure 24 shows the I2C Master reading data from a slave with a 10-bit address. In the Slave, this mode is enabled by setting I2C_SLAVE_ADDR_10BIT_EN register. In the Master, two bytes of RAM are used for a 10-bit address.

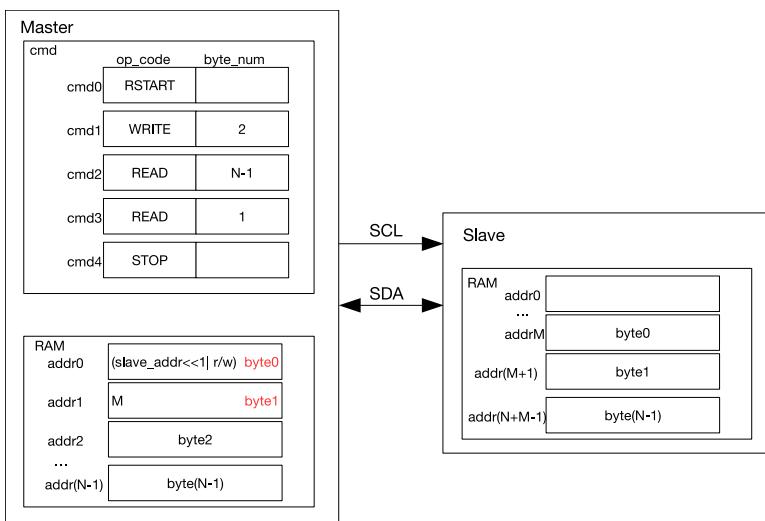

Figure 25: I2C Master Reads N Bytes of Data from addrM in Slave with 7-bit Address

Figure 25 shows the I2C Master selecting a register address inside the I2C Slave device and then reading data from it and subsequent addresses. This mode is enabled by setting the I2C_FIFO_ADDR_CFG_EN register in the Slave. The internal register address of the Slave, M, is stored in the RAM byte following the address. The WRITE command has a length of two data bytes to compensate for this.

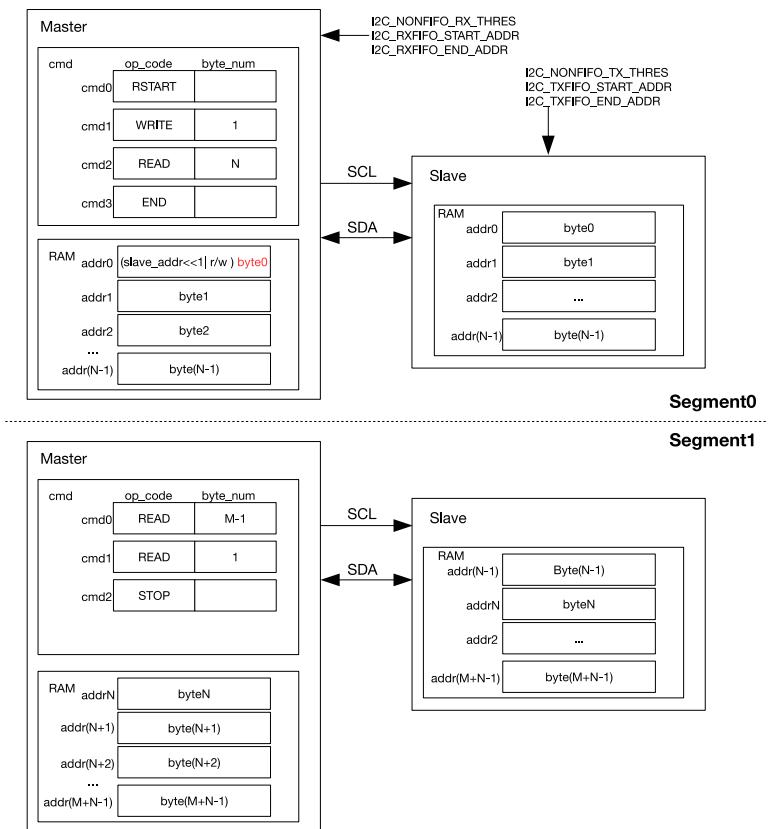

Figure 26: I2C Master Reads from Slave with 7-bit Address in Two Segments

Figure 26 shows the I2C Master reading N+M bytes of data in two segments from I2C Slave by using the END command. This allows for more data to be read than what can be fitted into the RAM. The upper part of the figure shows the configuration of Segment0. The Master will update the configuration of cmd after executing the END command, as shown in the lower part of the figure. I2C Slave will refresh the data before its RAM is empty.

6.3.7 Interrupts

- I2C_TX_SEND_EMPTY_INT: Triggered when I2C sends more data than nonfifo_tx_thres.
- I2C_RX_REC_FULL_INT: Triggered when I2C receives more data than nonfifo_rx_thres.
- I2C_ACK_ERR_INT: Triggered when I2C receives a wrong ACK bit..
- I2C_TRANS_START_INT: Triggered when I2C sends the START bit.
- I2C_TIME_OUT_INT: Triggered when I2C takes too long to receive data.
- I2C_TRANS_COMPLETE_INT: Triggered when I2C Master has finished STOP command or when I2C Slave detects STOP bit.
- I2C_MASTER_TRAN_COMP_INT: Triggered when I2C Master sends or receives a byte.
- I2C_ARBITRATION_LOST_INT: Triggered when I2C Master has lost the usage right of I2C Bus.
- I2C_END_DETECT_INT: Triggered when I2C deals with the END command.

6.4 Register Summary

Name	Description	I2C0	I2C1	Acc
Configuration registers				
I2C_SLAVE_ADDR_REG	Configures the I2C slave address	0x3FF53010	0x3FF67010	R/W
I2C_RXFIFO_ST_REG	FIFO status register	0x3FF53014	0x3FF67014	RO
I2C_FIFO_CONF_REG	FIFO configuration register	0x3FF53018	0x3FF67018	R/W

6.5 Registers

Register 6.1: I2C_SCL_LOW_PERIOD_REG (0x0000)

31	(reserved)															14	13	I2C_SCL_LOW_PERIOD															0
0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	Reset		

I2C_SCL_LOW_PERIOD This register is used to configure the low-level width of the SCL clock signal, in APB clock cycles. (R/W)

Register 6.2: I2C_CTR_REG (0x0004)

31	(reserved)															8	7	6	5	4	3	2	1	0		
0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1	1	Reset

I2C_RX_LSB_FIRST This bit is used to control the storage mode for received data. (R/W)

- 1: receive data from the least significant bit;
- 0: receive data from the most significant bit.

I2C_TX_LSB_FIRST This bit is used to control the sending mode for data needing to be sent. (R/W)

- 1: send data from the least significant bit;
- 0: send data from the most significant bit.

I2C_TRANS_START Set this bit to start sending the data in txfifo. (R/W)

I2C_MS_MODE Set this bit to configure the module as an I2C Master. Clear this bit to configure the module as an I2C Slave. (R/W)

I2C_SAMPLE_SCL_LEVEL 1: sample SDA data on the SCL low level; 0: sample SDA data on the SCL high level. (R/W)

I2C_SCL_FORCE_OUT 0: direct output; 1: open drain output. (R/W)

I2C_SDA_FORCE_OUT 0: direct output; 1: open drain output. (R/W)

Register 6.3: I2C_SR_REG (0x0008)

	(reserved)	I2C_SCL_STATE_LAST	(reserved)	I2C_SCL_MAIN_STATE_LAST	I2C_TXFIFO_CNT	(reserved)	I2C_RXFIFO_CNT	(reserved)	I2C_BYTE_TRANS	I2C_SLAVE_ADDRESSED	(reserved)	I2C_BUS_BUSY	I2C_ARB_LOST	I2C_TIME_OUT	I2C_SLAVE_RW	I2C_ACK_REC	Reset

0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	

I2C_TXFIFO_CNT This field stores the amount of received data in RAM. (RO)

I2C_RXFIFO_CNT This field represents the amount of data needed to be sent. (RO)

I2C_BYTE_TRANS This field changes to 1 when one byte is transferred. (RO)

I2C_SLAVE_ADDRESSED When configured as an I2C Slave, and the address sent by the master is equal to the address of the slave, then this bit will be of high level. (RO)

I2C_BUS_BUSY 1: the I2C bus is busy transferring data; 0: the I2C bus is in idle state. (RO)

I2C_ARB_LOST When the I2C controller loses control of SCL line, this register changes to 1. (RO)

I2C_TIME_OUT When the I2C controller takes more than I2C_TIME_OUT clocks to receive a data bit, this field changes to 1. (RO)

I2C_SLAVE_RW When in slave mode, 1: master reads from slave; 0: master writes to slave. (RO)

I2C_ACK_REC This register stores the value of the received ACK bit. (RO)

Register 6.4: I2C_TO_REG (0x000c)

	(reserved)	I2C_TIME_OUT	0
31	20	19	0
0	0	0	0

I2C_TIME_OUT This register is used to configure the timeout for receiving a data bit in APB clock cycles. (R/W)

Register 6.5: I2C_SLAVE_ADDR_REG (0x0010)

31	30		15	14		0
0	0	0	0	0	0	0

Reset

I2C_SLAVE_ADDR_10BIT_EN This field is used to enable the slave 10-bit addressing mode. (R/W)

I2C_SLAVE_ADDR When configured as an I2C Slave, this field is used to configure the slave address. (R/W)

Register 6.6: I2C_RXFIFO_ST_REG (0x0014)

31		20	19	15	14	10	9	5	4	0
0	0	0	0	0	0	0	0	0	0	0

Reset

I2C_TXFIFO_END_ADDR This is the offset address of the last sent data, as described in non-fifo_tx_thres register. (RO)

I2C_TXFIFO_START_ADDR This is the offset address of the first sent data, as described in non-fifo_tx_thres register. (RO)

I2C_RXFIFO_END_ADDR This is the offset address of the first received data, as described in non-fifo_rx_thres_register. (RO)

I2C_RXFIFO_START_ADDR This is the offset address of the last received data, as described in non-fifo_rx_thres_register. (RO)

Register 6.7: I2C_FIFO_CONF_REG (0x0018)

Reset									

I2C_NONFIFO_TX_THRES When I2C sends more than nonfifo_tx_thres bytes of data, it will generate a tx_send_empty_int_raw interrupt and update the current offset address of the sent data. (R/W)

I2C_NONFIFO_RX_THRES When I2C receives more than nonfifo_rx_thres bytes of data, it will generate a rx_send_full_int_raw interrupt and update the current offset address of the received data. (R/W)

I2C_FIFO_ADDR_CFG_EN When this bit is set to 1, the byte received after the I2C address byte represents the offset address in the I2C Slave RAM. (R/W)

I2C_NONFIFO_EN Set this bit to enable APB nonfifo access. (R/W)

I2C_SDA_FILTER_EN This is the filter enable bit for SDA. (R/W)

I2C_SDA_FILTER_THRES When a pulse on the SDA input has smaller width than this register value in APB clock cycles, the I2C controller will ignore that pulse. (R/W)

Register 6.21: I2C_COMMANDn_REG ($n: 0-15$) (0x58+4*n)

31	30	14	13	0
0	0 0	0	0 0	Reset

I2C_COMMANDn_DONE When command n is done in I2C Master mode, this bit changes to high level. (R/W)

I2C_COMMANDn This is the content of command n . It consists of three parts: (R/W)
op_code is the command, 0: RSTART; 1: WRITE; 2: READ; 3: STOP; 4: END.

Byte_num represents the number of bytes that need to be sent or received.

ack_check_en, ack_exp and ack are used to control the ACK bit. See [I2C cmd structure](#) for more information.

7. I2S

7.1 Overview

The I2S bus provides a flexible communication interface for streaming digital data in multimedia applications, especially digital audio applications. The ESP32 includes two I2S interfaces: I2S0 and I2S1.

The I2S standard bus defines three signals: a clock signal, a channel selection signal, and a serial data signal. A basic I2S data bus has one master and one slave. The roles remain unchanged throughout the communication. The I2S modules on the ESP32 provide separate transmit and receive channels for high performance.

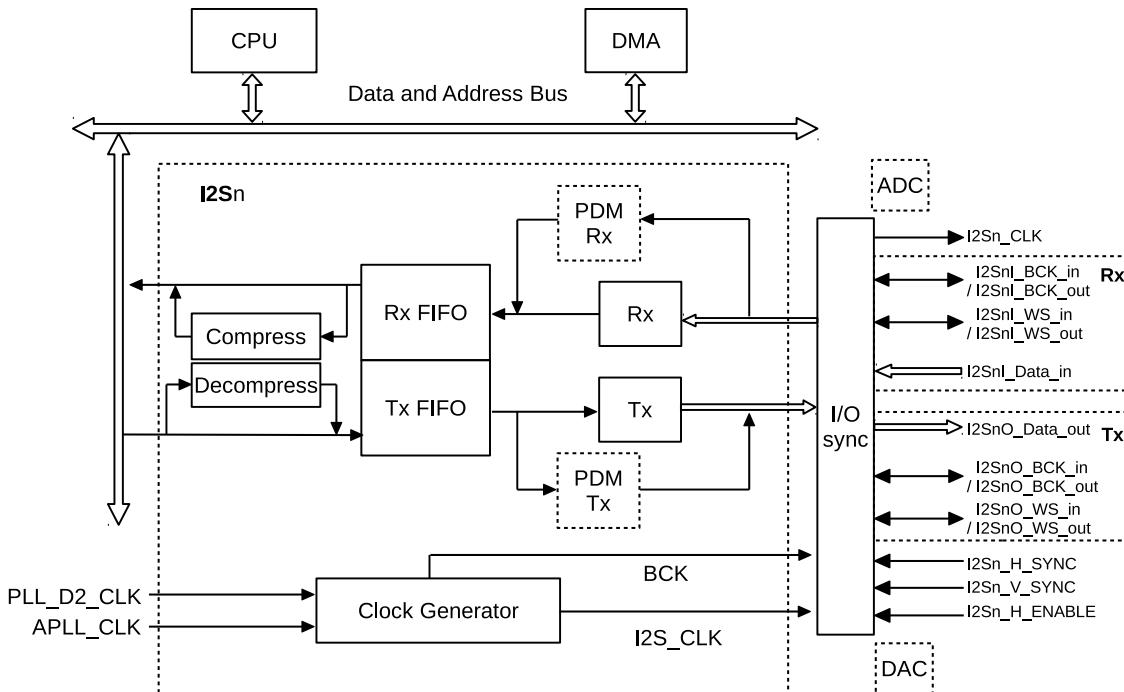

Figure 27: I2S System Block Diagram

Figure 27 is the system block diagram of the ESP32 I2S module. In the figure above, the value of "*n*" can be either 0 or 1. There are two independent I2S modules embedded in ESP32, namely I2S0 and I2S1. Each I2S module contains a Tx (transmit) unit and a Rx (receive) unit. Both the Tx unit and the Rx unit have a three-wire interface that includes a clock line, a channel selection line and a serial data line. The serial data line of the Tx unit is fixed as output, and the serial data line of the receive unit is fixed as input. The clock line and the channel selection line of the Tx and Rx units can be configured to both master transmitting mode and slave receiving mode. In the LCD mode, the serial data line extends to the parallel data bus. Both the Tx unit and the Rx unit have a 32-bit-wide FIFO with a depth of 64. Besides, only I2S0 supports on-chip DAC/ADC modes, as well as receiving and transmitting PDM signals.

The right side of Figure 27 shows the signal bus of the I2S module. The signal naming rule of the Rx and Tx units is I2S*n*A_B_C, where "*n*" stands for either I2S0 or I2S1; "A" represents the direction of I2S module's data bus signal, "I" represents input, "O" represents output; "B" represents signal function; "C" represents the signal direction, "in" means that the signal is input into the I2S module, while "out" means that the I2S module outputs the signal. For a detailed description of the I2S signal bus, please refer to Table 27.

Table 27: I2S Signal Bus Description

Signal Bus	Signal Direction	Data Signal Direction
I2S _n I_BCK_in	In slave mode, I2S module accepts signals.	I2S module receives data.
I2S _n I_BCK_out	In master mode, I2S module outputs signals.	I2S module receives data.
I2S _n I_WS_in	In slave mode, I2S module accepts signals.	I2S module receives data.
I2S _n I_WS_out	In master mode, I2S module outputs signals.	I2S module receives data.
I2S _n I_Data_in	I2S module accepts signals.	In I2S mode, I2S _n I_Data_in[15] is the serial data bus of I2S. In LCD mode, the data bus width can be configured as needed.
I2S _n O_Data_out	I2S module outputs signals.	In I2S mode, I2S _n O_Data_out[23] is the serial data bus of I2S. In LCD mode, the data bus width can be configured as needed.
I2S _n O_BCK_in	In slave mode, I2S module accepts signals.	I2S module sends data.
I2S _n O_BCK_out	In master mode, I2S module outputs signals.	I2S module sends data.
I2S _n O_WS_in	In slave mode, I2S module accepts signals.	I2S module sends data.
I2S _n O_WS_out	In master mode, I2S module outputs signals.	I2S module sends data.
I2S _n _CLK	I2S module outputs signals.	It is used as a clock source for peripheral chips.
I2S _n _H_SYNC I2S _n _V_SYNC I2S _n _H_ENABLE	In Camera mode, I2S module accepts signals.	The signals are sent from the Camera.

Table 27 describes the signal bus of the I2S module. Except for the I2S_n_CLK signal, all other signals are mapped to the chip pin via the GPIO matrix and IO MUX. The I2S_n_CLK signal is mapped to the chip pin via the IO_MUX. For details, please refer to the chapter about [IO_MUX and the GPIO Matrix](#).

7.2 Features

I2S mode

- Configurable high-precision output clock
- Full-duplex and half-duplex data transmit and receive modes
- Supports multiple digital audio standards
- Embedded A-law compression/decompression module
- Configurable clock signal
- Supports PDM signal input and output
- Configurable data transmit and receive modes

LCD mode

- Supports multiple LCD modes, including external LCD
- Supports external Camera

- Supports on-chip DAC/ADC modes

I2S interrupts

- Standard I2S interface interrupts
- I2S DMA interface interrupts

7.3 The Clock of I2S Module

As is shown in Figure 28, I2S_n_CLK, as the master clock of I2S module, is derived from the 160 MHz clock PLL_D2_CLK or the configurable analog PLL output clock APLL_CLK. The serial clock (BCK) of the I2S module is derived from I2S_n_CLK. The I2S_CLKA_ENA bit of register I2S_CLKM_CONF_REG is used to select either PLL_D2_CLK or APLL_CLK as the clock source for I2S_n. PLL_D2_CLK is used as the clock source for I2S_n, by default. For high performance audio applications, the analog PLL output clock source APLL_CLK must be used to acquire highly accurate I2S_n_CLK and BCK. For further details, please refer to the chapter entitled [Reset and Clock](#).

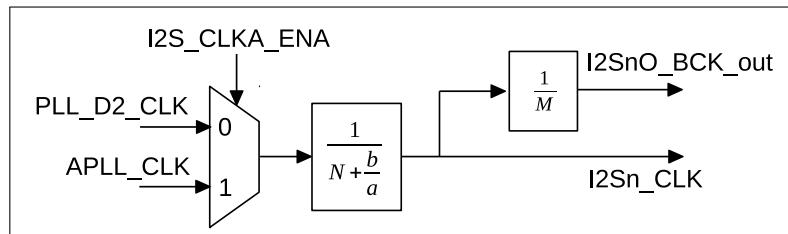

Figure 28: I2S Clock

The relation between I2S_n_CLK frequency f_{i2s} and the divider clock source frequency f_{pll} can be seen in the equation below:

$$f_{i2s} = \frac{f_{pll}}{N + \frac{b}{a}}$$

"N" corresponds to the REG _CLKM_DIV_NUM [7: 0] bits of register I2S_CLKM_CONF_REG , "b" is the I2S_CLKM_DIV_B[5:0] bit and "a" is the I2S_CLKM_DIV_A[5:0] bit.

In master mode, the serial clock BCK in the I2S module is derived from I2S_n_CLK, that is:

$$f_{BCK} = \frac{f_{i2s}}{M}$$

In master transmitting mode, "M" is the I2S_TX_BCK_DIV_NUM[5:0] bit of register I2S_SAMPLE_RATE_CONF_REG. In master receiving mode, "M" is the I2S_RX_BCK_DIV_NUM[5:0] bit of register I2S_SAMPLE_RATE_CONF_REG.

7.4 I2S Mode

The ESP32 I2S module integrates an A-law compression/decompression module to enable compression/decompression of the received audio data. The RX_PCM_BYPASS bit and the TX_PCM_BYPASS bit of register I2SCONF1_REG should be cleared when using the A-law compression/decompression module.

7.4.1 Supported Audio Standards

In the I2S bus, BCK is the serial clock, WS is the left- /right-channel selection signal (also called word select signal), and SD is the serial data signal for transmitting/receiving digital audio data. WS and SD signals in the I2S module change on the falling edge of BCK, while the SD signal can be sampled on the rising edge of BCK. If the I2S_RX_RIGHT_FIRST bit and the I2S_TX_RIGHT_FIRST bit of register I2SCONF_REG are set to 1, the I2S module is configured to receive and transmit right-channel data first. Otherwise, the I2S module receives and transmits left-channel data first.

7.4.1.1 Philips Standard

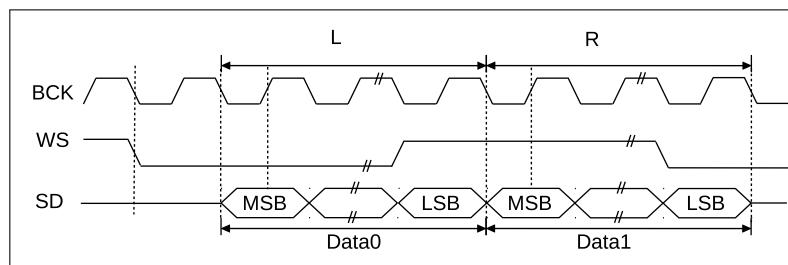

Figure 29: Philips Standard

As is shown in Figure 29, the Philips I2S bus specifications require that the WS signal starts to change a BCK clock cycle earlier than the SD signal, which means that the WS signal takes effect a clock cycle before the first bit of the current channel-data transmission, while the WS signal continues until the end of the current channel-data transmission. The SD signal line transmits the most significant bit of audio data first. If the I2S_RX_MSB_SHIFT bit and the I2S_TX_MSB_SHIFT bit of register I2SCONF_REG are set to 1, respectively, the I2S module will use the Philips standard when receiving and transmitting data.

7.4.1.2 MSB Alignment Standard

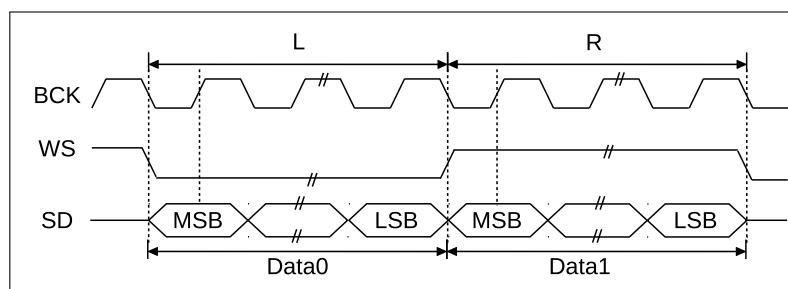

Figure 30: MSB Alignment Standard

The MSB alignment standard is shown in Figure 30. WS and SD signals both change simultaneously on the falling edge of BCK under the MSB alignment standard. The WS signal continues until the end of the current channel-data transmission, and the SD signal line transmits the most significant bit of audio data first. If the I2S_RX_MSB_SHIFT and I2S_TX_MSB_SHIFT bits of register I2SCONF_REG are cleared, the I2S module will use the MSB alignment standard when receiving and transmitting data.

7.4.1.3 PCM Standard

As is shown in Figure 31, under the short frame synchronization mode of the PCM standard, the WS signal starts to change a BCK clock cycle earlier than the SD signal, which means that the WS signal takes effect a clock cycle earlier than the first bit of the current channel-data transmission and continues for one extra BCK clock cycle. The SD signal line transmits the most significant bit of audio data first. If the I2S_RX_SHORT_SYNC and I2S_TX_SHORT_SYNC bits of register I2SCONF_REG are set, the I2S module will receive and transmit data in the short frame synchronization mode.

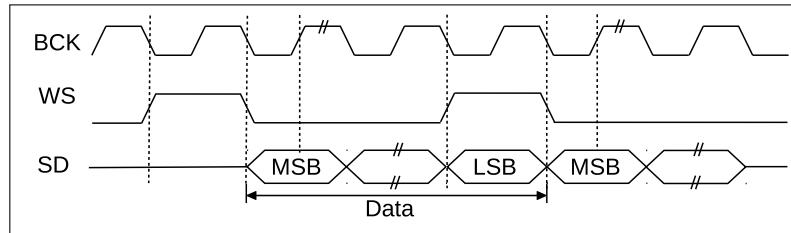

Figure 31: PCM Standard

7.4.2 Module Reset

The four low-order bits in register I2SCONF_REG, that is, I2S_TX_RESET, I2S_RX_RESET, I2S_TX_FIFO_RESET and I2S_RX_FIFO_RESET reset the receive module, the transmit module and the corresponding FIFO buffer, respectively. In order to finish a reset operation, the corresponding bit should be set and then cleared by software.

7.4.3 FIFO Operation

The data read/write packet length for a FIFO operation is 32 bits. The data packet format for the FIFO buffer can be configured using configuration registers. As shown in Figure 27, both sent and received data should be written into FIFO first and then read from FIFO. There are two approaches to accessing the FIFO; one is to directly access the FIFO using a CPU, the other is to access the FIFO using a DMA controller.

Generally, both the I2S_RX_FIFO_MOD_FORCE_EN bit and I2S_TX_FIFO_MOD_FORCE_EN bits of register I2S_FIFO_CONF_REG should be set to 1. I2S_TX_DATA_NUM[5:0] bit and I2S_RX_DATA_NUM[5:0] are used to control the length of the data that have been sent, received and buffered. Hardware inspects the received-data length RX_LEN and the transmitted-data length TX_LEN. Both the received and the transmitted data are buffered in the FIFO method.

When RX_LEN is greater than I2S_RX_DATA_NUM[5:0], the received data, which is buffered in FIFO, has reached the set threshold and needs to be read out to prevent an overflow. When TX_LEN is less than I2S_TX_DATA_NUM[5:0], the transmitted data, which is buffered in FIFO, has not reached the set threshold and software can continue feeding data into FIFO.

7.4.4 Sending Data

The ESP32 I2S module carries out a data-transmit operation in three stages:

- Read data from internal storage and transfer it to FIFO
- Read data to be sent from FIFO

- Clock out data serially, or in parallel, as configured by the user

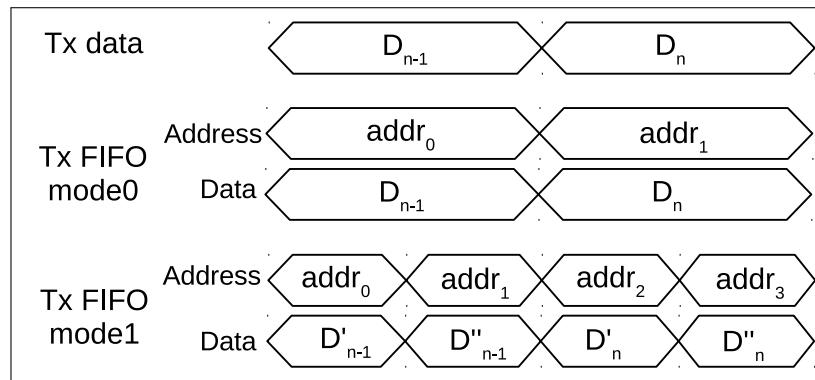

Figure 32: Tx FIFO Data Mode

Table 28: Register Configuration

	I2S_TX_FIFO_MOD[2:0]	Description
Tx FIFO mode0	0	16-bit dual channel data
	2	32-bit dual channel data
	3	32-bit single channel data
Tx FIFO mode1	1	16-bit single channel data

At the first stage, there are two modes for data to be sent and written into FIFO. In Tx FIFO mode0, the Tx data-to-be-sent are written into FIFO according to the time order. In Tx FIFO mode1, the data-to-be-sent are divided into 16 high- and 16 low-order bits. Then, both the 16 high- and 16 low-order bits are recomposed and written into FIFO. The details are shown in Figure 32 with the corresponding registers listed in Table 28. D'_n consists of 16 high-order bits of D_n and 16 zeros. D''_n consists of 16 low-order bits of D_n and 16 zeros. That is to say, $D'_n = \{D_n[31 : 16], 16'h0\}$, $D''_n = \{D_n[15 : 0], 16'h0\}$.

At the second stage, the system reads data that will be sent from FIFO, according to the relevant register configuration. The mode in which the system reads data from FIFO is relevant to the configuration of I2S_TX_FIFO_MOD[2:0] and I2S_TX_CHAN_MOD[2:0]. I2S_TX_FIFO_MOD[2:0] determines whether the data are 16-bit or 32-bit, as shown in Table 28, while I2S_TX_CHAN_MOD[2:0] determines the format of the data-to-be-sent, as shown in Table 29.

Table 29: Send Channel Mode

I2S_TX_CHAN_MOD[2:0]	Description
0	Dual channel mode
1	Mono mode When I2S_TX_MSB_RIGHT equals 0, the left-channel data are "holding" their values and the right-channel data change into the left-channel data. When I2S_TX_MSB_RIGHT equals 1, the right-channel data are "holding" their values and the left-channel data change into the right-channel data.
2	Mono mode When I2S_TX_MSB_RIGHT equals 0, the right-channel data are "holding" their values and the left-channel data change into the right-channel data. When I2S_TX_MSB_RIGHT equals 1, the left-channel data are "holding" their values and the right-channel data change into the left-channel data.

I2S_TX_CHAN_MOD[2:0]	Description
3	Mono mode When I2S_TX_MSB_RIGHT equals 0, the left-channel data are constants in the range of REG[31:0]. When I2S_TX_MSB_RIGHT equals 1, the right-channel data are constants in the range of REG[31:0].
4	Mono mode When I2S_TX_MSB_RIGHT equals 0, the right-channel data are constants in the range of REG[31:0]. When I2S_TX_MSB_RIGHT equals 1, the left-channel data are constants in the range of REG[31:0].

REG[31:0] is the value of register I2SCONF_SIGLE_DATA_REG[31:0].

The output of the third stage is determined by the mode of the I2S and I2S_TX_BITS_MOD[5:0] bits of register I2S_SAMPLE_RATE_CONF_REG.

7.4.5 Receiving Data

The data-receive phase of the ESP32 I2S module consists of another three stages:

- The input serial-bit stream is transformed into a 64-bit parallel-data stream in I2S mode. In LCD mode, the input parallel-data stream will be extended to a 64-bit parallel-data stream.
- Received data are written into FIFO.
- Data are read from FIFO by CPU/DMA and written into the internal memory.

At the first stage of receiving data, the received-data stream is expanded to a zero-padded parallel-data stream with 32 high-order bits and 32 low-order bits, according to the level of the I2S_n_WS_out (or I2S_n_WS_in) signal. The I2S_RX_MSB_RIGHT bit of register I2SCONF_REG is used to determine how the data are to be expanded.

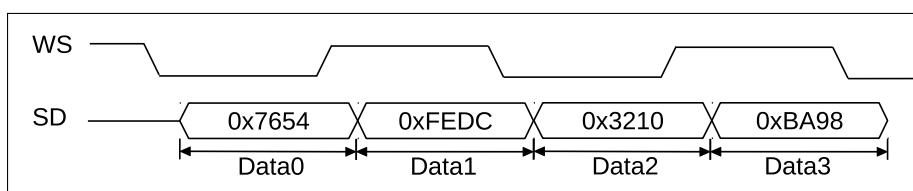

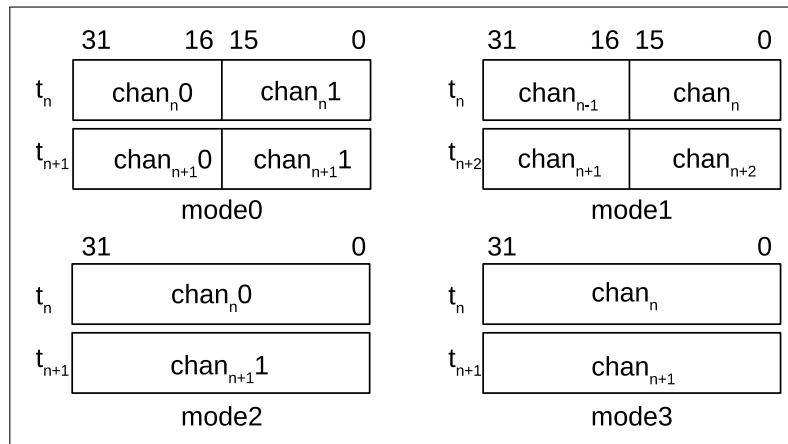

Figure 33: The First Stage of Receiving Data

For example, as is shown in Figure 33, if the width of serial data is 16 bits, when I2S_RX_RIGHT_FIRST equals 1, Data0 will be discarded and I2S will start receiving data from Data1. If I2S_RX_MSB_RIGHT equals 1, data of the first stage would be {0xFEDC0000, 0x32100000}. If I2S_RX_MSB_RIGHT equals 0, data of the first stage would be {0x32100000, 0xFEDC0000}. When I2S_RX_RIGHT_FIRST equals 0, I2S will start receiving data from Data0. If I2S_RX_MSB_RIGHT equals 1, data of the first stage would be {0xFEDC0000, 0x76540000}. If I2S_RX_MSB_RIGHT equals 0, data of the first stage would be {0x76540000, 0xFEDC0000}.

As is shown in Table 30 and Figure 34, at the second stage, the received data of the Rx unit is written into FIFO. There are four modes of writing received data into FIFO. Each mode corresponds to a value of I2S_RX_FIFO_MOD[2:0] bit.

Table 30: Modes of Writing Received Data into FIFO and the Corresponding Register Configuration

I2S_RX_FIFO_MOD[2:0]	Data format
0	16-bit dual channel data
1	16-bit single channel data
2	32-bit dual channel data
3	32-bit single channel data

**Figure 34: Modes of Writing Received Data into FIFO**

At the third stage, CPU or DMA will read data from FIFO and write them into the internal memory directly. The register configuration that each mode corresponds to is shown in Table 31.

Table 31: The Register Configuration to Which the Four Modes Correspond

I2S_RX_MSB_RIGHT	I2S_RX_CHAN_MOD	mode0	mode1	mode2	mode3
0	0	left channel + right channel	-	left channel + right channel	-
	1		left channel + left channel		left channel + left channel
	2		right channel + right channel		right channel + right channel
	3		-		-
1	0	right channel + left channel	-	right channel + left channel	-
	1		right channel + right channel		right channel + right channel
	2		left channel + left channel		left channel + left channel
	3		-		-

7.4.6 I2S Master/Slave Mode

The ESP32 I2S module can be configured to act as a master or slave device on the I2S bus. The module supports slave transmitter and receiver configurations in addition to master transmitter and receiver configurations. All these modes can support full-duplex and half-duplex communication over the I2S bus.

I2S_RX_SLAVE_MOD bit and I2S_TX_SLAVE_MOD bit of register I2SCONF_REG can configure I2S to slave receiving mode and slave transmitting mode, respectively.

I2S_TX_START bit of register I2SCONF_REG is used to enable transmission. When I2S is in master transmitting mode and this bit is set, the module will keep driving the clock signal and data of left and right channels. If FIFO sends out all the buffered data and there are no new data to shift, the last batch of data will be looped on the data line. When this bit is reset, master will stop driving clock and data lines. When I2S is configured to slave transmitting mode and this bit is set, the module will wait for the master BCK clock to enable a transmit operation.

The I2S_RX_START bit of register I2SCONF_REG is used to enable a receive operation. When I2S is in master transmitting mode and this bit is set, the module will keep driving the clock signal and sampling the input data stream until this bit is reset. If I2S is configured to slave receiving mode and this bit is set, the receiving module will wait for the master BCK clock to enable a receiving operation.

7.4.7 I2S PDM

As is shown in Figure 27, ESP32 I2S0 allows for pulse density modulation (PDM), which enables fast conversion between pulse code modulation (PCM) and PDM signals.

The output clock of PDM is mapped to the I2S0*_WS_out signal. Its configuration is identical to I2S's BCK. Please refer to section 7.3, "The Clock of I2S Module", for further details. The bit width for both received and transmitted I2S PCM signals is 16 bits.

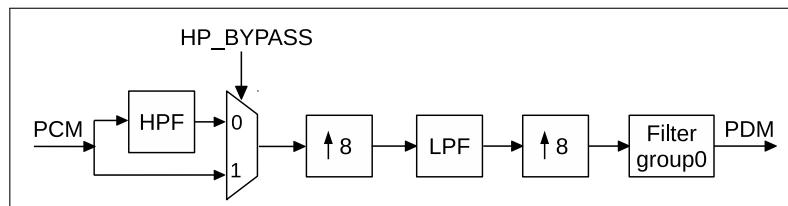

Figure 35: PDM Transmitting Module

The PDM transmitting module is used to convert PCM signals into PDM signals, as shown in Figure 35. HPF is a high-speed channel filter, and LPF is a low-speed channel filter. The PDM signal is derived from the PCM signal, after upsampling and filtering. Signal I2S_TX_PDM_HP_BYPASS of register I2S_PDM_CONF_REG can be set to bypass the HPF at the PCM input. Filter module group0 carries out the upsampling. If the frequency of the PDM signal is f_{pdm} and the frequency of the PCM signal is f_{pcm} , the relation between f_{pdm} and f_{pcm} is given by:

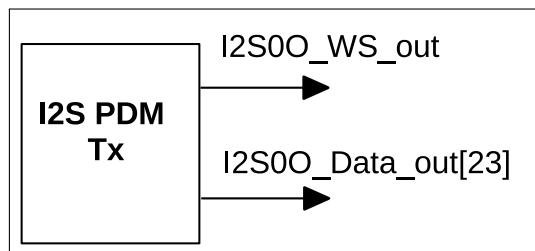

$$f_{\text{pdm}} = f_{\text{pcm}} * 64 * \text{I2S_TX_PDM_SINC_OSR2}$$

The upsampling factor of 64 is the result of the two upsampling stages. The I2S_TX_PDM_SINC_OS2 bit of register I2S_PDM_CONF_REG is the upsampling rate of filter module group0.

Table 32 lists the configuration rates of the I2S_TX_PDM_FP bit and the I2S_TX_PDM_FS bit of register I2S_PDM_FREQ_CONF_REG, whose output PDM signal frequency remains 48*128 KHz at different PCM signal frequencies.

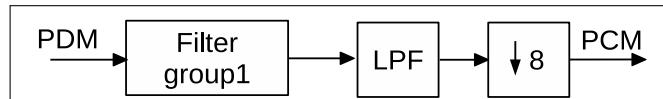

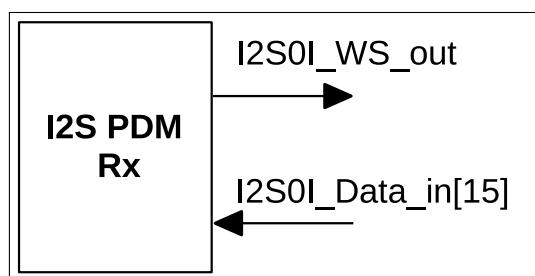

Table 32: Upsampling Rate Configuration

f_{pcm} (KHz)	I2S_TX_PDM_SINC_OSR2	I2S_TX_PDM_FP	I2S_TX_PDM_FS	f_{pdm} (KHz)
48	2	960	480	48*128
44.1	2	960	441	
32	3	960	320	
24	4	960	240	
16	6	960	160	
8	12	960	80	

**Figure 36: PDM Sends Signal**

As is shown in Figure 36, the I2S_TX_PDM_EN bit and the I2S_PCM2PDM_CONV_EN bit of register I2S_PDM_CONF_REG should be set to 1 to use the PDM sending module.

The I2S_TX_PDM_SIGMADELTA_IN_SHIFT bit, I2S_TX_PDM_SINC_IN_SHIFT bit, I2S_TX_PDM_LP_IN_SHIFT bit and I2S_TX_PDM_HP_IN_SHIFT bit of register I2S_PDM_CONF_REG are used to adjust the size of the input signal of each filter module.

**Figure 37: PDM Transmit Module****Figure 38: PDM Receives Signal**

As is shown in Figure 38, the I2S_RX_PDM_EN bit and the I2S_PDM2PCM_CONV_EN bit of register I2S_PDM_CONF_REG should be set to 1, in order to use the PDM receiving module. As is shown in Figure 37, the PDM receiving module will convert the received PDM signal into a 16-bit PCM signal. Filter group1 is used to downsample the PDM signal, and the I2S_RX_PDM_SINC_DSR_16_EN bit of register I2S_PDM_CONF_REG is used to adjust the corresponding down-sampling rate. Table 33 shows the configuration of the I2S_RX_PDM_SINC_DSR_16_EN bit whose PCM signal frequency remains 48 KHz at different PDM signal frequencies.

Table 33: Down-sampling Configuration

PDM freq (KHz)	I2S_RX_PDM_SINC_DSR_16_EN	PCM freq (KHz)
48*128	1	48
48*64	0	

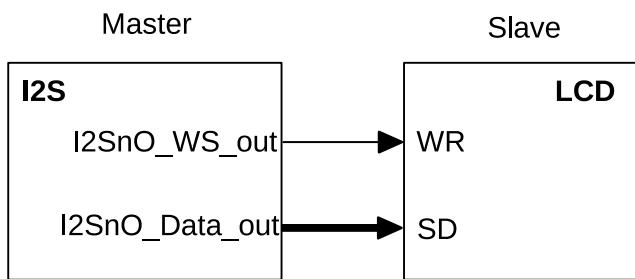

7.5 LCD Mode

There are three operational modes in the LCD mode of ESP32 I2S:

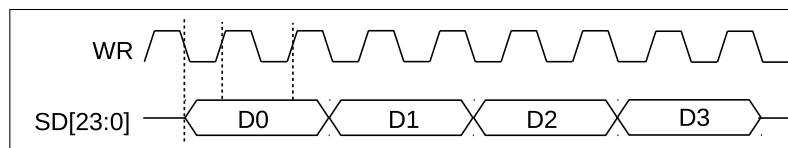

- LCD master transmitting mode
- Camera slave receiving mode
- ADC/DAC mode

7.5.1 LCD Master Transmitting Mode

The clock configuration of the LCD master transmitting mode is identical to I2S's clock configuration. As is shown in Figure 39, the WR signal of LCD connects to the WS signal of I2S. The LCD data bus width is 24 bits.

**Figure 39: LCD Master Transmitting Mode**

The I2S_LCD_EN bit of register I2SCONF2_REG needs to be set and the I2S_TX_SLAVE_MOD bit of register I2SCONF_REG needs to be cleared, in order to configure I2S to the LCD master transmitting mode. Meanwhile, data should be sent under the correct mode, according to the I2S_TX_CHAN_MOD[2:0] bit of register I2SCONF_CHAN_REG and the I2S_TX_FIFO_MOD[2:0] bit of register I2S_FIFO_CONF_REG. The WS signal needs to be inverted when it is routed through the GPIO Matrix. For details, please refer to the chapter about [IO_MUX](#) and the [GPIO Matrix](#). The I2S_LCD_TX_SDX2_EN bit and the I2S_LCD_TX_WRX2_EN bit of register I2SCONF2_REG should be set to the LCD master transmitting mode, so that both the data bus and WR signal work in the appropriate mode.

**Figure 40: LCD Master Transmitting Data Frame, Form 1**

As is shown in Figure 40 and Figure 41, the I2S_LCD_TX_WRX2_EN bit should be set to 1 and the I2S_LCD_TX_SDX2_EN bit should be set to 0 in the data frame, form 1. Both I2S_LCD_TX_SDX2_EN bit and I2S_LCD_TX_WRX2_EN bit are set to 1 in the data frame, form 2.

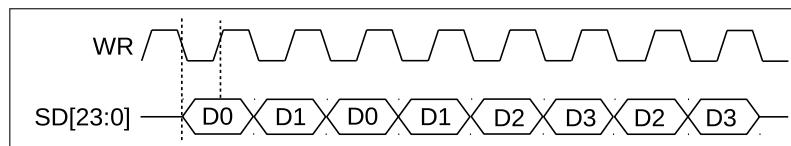

Figure 41: LCD Master Transmitting Data Frame, Form 2

7.5.2 Camera Slave Receiving Mode

ESP32 I2S supports a camera slave mode for high-speed data transfer from external camera modules. As shown in Figure 42, in this mode, I2S is set to slave receiving mode. Besides the 16-channel data signal bus I2S_nI_Data_in, there are other signals, such as I2S_nH_SYNC, I2S_nV_SYNC and I2S_nH_ENABLE.

The PCLK in the Camera module connects to I2S_nI_WS_in in the I2S module, as Figure 42 shows.

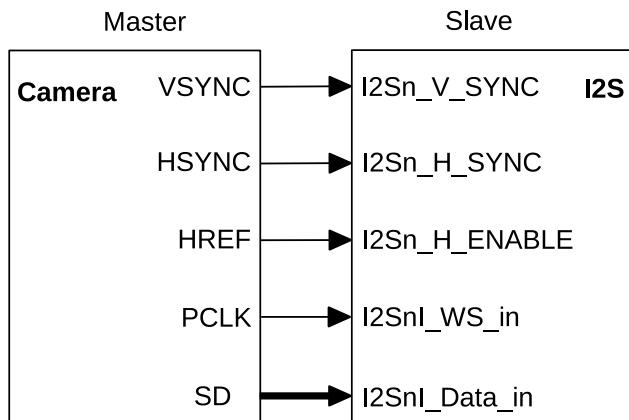

Figure 42: Camera Slave Receiving Mode

When I2S is in the camera slave receiving mode, and when I2S_nH_SYNC, I2S_nV_SYNC and I2S_nH_REF are held high, the master starts transmitting data, that is,

$$\text{transmission_start} = (\text{I2S}_n\text{H_SYNC} == 1) \&\& (\text{I2S}_n\text{V_SYNC} == 1) \&\& (\text{I2S}_n\text{H_ENABLE} == 1)$$

Thus, during data transmission, these three signals should be kept at a high level. For example, if the I2S_nV_SYNC signal of a camera is at low level during data transmission, it will be inverted when routed to the I2S module. ESP32 supports signal inversion through the GPIO matrix. For details, please refer to the chapter about [IO_MUX and the GPIO Matrix](#).

In order to make I2S work in camera mode, the I2S_LCD_EN bit and the I2S_CAMERA_EN bit of register I2SCONF2_REG are set to 1, the I2S_RX_SLAVE_MOD bit of register I2SCONF_REG is set to 1, the I2S_RX_MSB_RIGHT bit and the I2S_RX_RIGHT_FIRST bit of I2SCONF_REG are set to 0. Thus, I2S works in the LCD slave receiving mode. At the same time, in order to use the correct mode to receive data, both the I2S_RX_CHAN_MOD[2:0] bit of register I2SCONF_CHAN_REG and the I2S_RX_FIFO_MOD[2:0] bit of register I2S_FIFO_CONF_REG are set to 1.

7.5.3 ADC/DAC mode

In LCD mode, ESP32's ADC and DAC can receive data. When the I2S0 module connects to the on-chip ADC, the I2S0 module should be set to master receiving mode. Figure 43 shows the signal connection between the I2S0 module and the ADC.

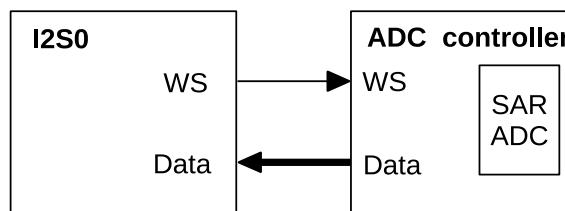

Figure 43: ADC Interface of I2S0

Firstly, the I2S_LCD_EN bit of register I2SCONF2_REG is set to 1, and the I2S_RX_SLAVE_MOD bit of register I2SCONF_REG is set to 0, so that the I2S0 module works in LCD master receiving mode, and the I2S0 module clock is configured such that the WS signal of I2S0 outputs an appropriate frequency. Then, the APB_CTRL_SARADC_DATA_TO_I2S bit of register APB_CTRL_APB_SARADC_CTRL_REG is set to 1. Enable I2S to receive data after configuring the relevant registers of SARADC. For details, please refer to the chapter about on-chip sensors.

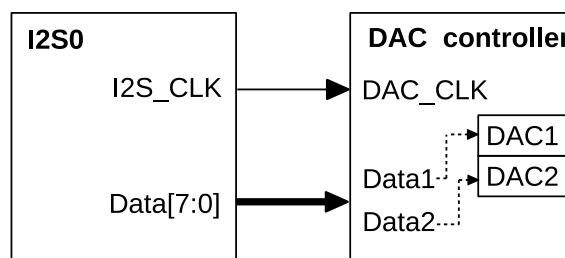

Figure 44: DAC Interface of I2S

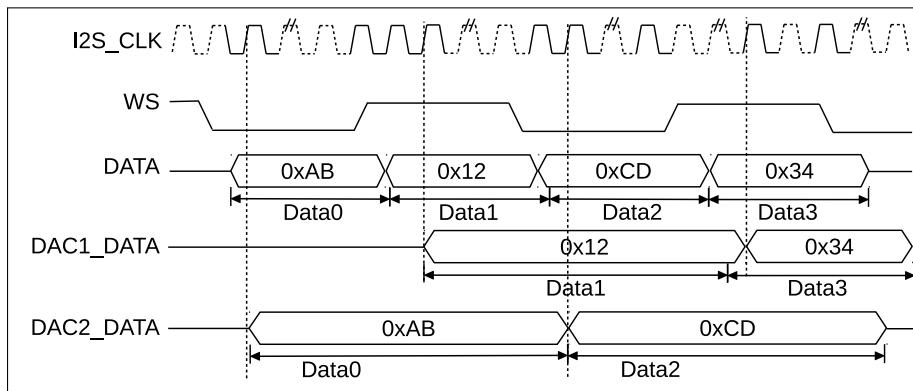

Figure 45: Data Input by I2S DAC Interface

The I2S0 module should be configured to master transmitting mode when it connects to the on-chip DAC. Figure 44 shows the signal connection between the I2S0 module and the DAC. The DAC's control module regards I2S_CLK as the clock in this configuration. As shown in Figure 45, when the data bus inputs data to the DAC's control module, the latter will input right-channel data to DAC1 module and left-channel data to DAC2 module. The toggle frequency of the WS signal is twice as that of the f_{BCK} , I2S_TX_BCK_DIV_NUM[5:0] bit of register I2S_SAMPLE_RATE_CONF_REG, which should be configured to achieve a suitable sampling rate. When using the I2S DMA module, 8 bits of data-to-be-transmitted are shifted to the left by 8 bits of data-to-be-received into the DMA double-byte type of buffer.

The I2S_LCD_EN bit of register I2SCONF2_REG should be set to 1, while I2S_RX_SHORT_SYNC, I2S_TX_SHORT_SYNC, I2SCONF_REG, I2S_RX_MSB_SHIFT and I2S_TX_MSB_SHIFT should all be reset to 0. The I2S_RX_SLAVE_MOD bit of register I2SCONF_REG should be set to 0, as well, when using the DAC mode of I2S0. Select a suitable transmit mode according to the standards of transmitting a 16-bit digital data stream.

Configure the I2S0 module clock to output a suitable frequency for the I2S_CLK and the WS of I2S. Enable I2S0 to send data after configuring the relevant DAC registers.

7.6 I2S Interrupts

7.6.1 FIFO Interrupts

- I2S_TX_HUNG_INT: Triggered when transmitting data is timed out.
- I2S_RX_HUNG_INT: Triggered when receiving data is timed out.
- I2S_TX_REMPTY_INT: Triggered when the transmit FIFO is empty.
- I2S_TX_WFULL_INT: Triggered when the transmit FIFO is full.
- I2S_RX_REMPTY_INT: Triggered when the receive FIFO is empty.
- I2S_RX_WFULL_INT: Triggered when the receive FIFO is full.
- I2S_TX_PUT_DATA_INT: Triggered when the transmit FIFO is almost empty.
- I2S_RX_TAKE_DATA_INT: Triggered when the receive FIFO is almost full.

7.6.2 DMA Interrupts

- I2S_OUT_TOTAL_EOF_INT: Triggered when all transmitting linked lists are used up.
- I2S_IN_DSCR_EMPTY_INT: Triggered when there are no valid receiving linked lists left.
- I2S_OUT_DSCR_ERR_INT: Triggered when invalid rxlink descriptors are encountered.
- I2S_IN_DSCR_ERR_INT: Triggered when invalid txlink descriptors are encountered.
- I2S_OUT_EOF_INT: Triggered when rxlink has finished sending a packet.
- I2S_OUT_DONE_INT: Triggered when all transmitted and buffered data have been read.
- I2S_IN_SUC_EOF_INT: Triggered when all data have been received.
- I2S_IN_DONE_INT: Triggered when the current txlink descriptor is handled.

I2S_SIG_LOOPBACK Enable signal loopback mode, with transmitter module and receiver module sharing the same WS and BCK signals. (R/W)

I2S_RX_MSB_RIGHT Set this to place right-channel data at the MSB in the receive FIFO. (R/W)

I2S_TX_MSB_RIGHT Set this bit to place right-channel data at the MSB in the transmit FIFO. (R/W)

I2S_RX_MONO Set this bit to enable receiver's mono mode. (R/W)

I2S_TX_MONO Set this bit to enable transmitter's mono mode. (R/W)

I2S_RX_SHORT_SYNC Set this bit to enable receiver in PCM standard mode. (R/W)

I2S_TX_SHORT_SYNC Set this bit to enable transmitter in PCM standard mode. (R/W)

I2S_RX_MSB_SHIFT Set this bit to enable receiver in Philips standard mode. (R/W)

I2S_TX_MSB_SHIFT Set this bit to enable transmitter in Philips standard mode. (R/W)

I2S_RX_RIGHT_FIRST Set this bit to receive right-channel data first. (R/W)

I2S_TX_RIGHT_FIRST Set this bit to transmit right-channel data first. (R/W)

I2S_RX_SLAVE_MOD Set this bit to enable slave receiver mode. (R/W)

I2S_TX_SLAVE_MOD Set this bit to enable slave transmitter mode. (R/W)

I2S_RX_START Set this bit to start receiving data. (R/W)

I2S_TX_START Set this bit to start transmitting data. (R/W)

I2S_RX_FIFO_RESET Set this bit to reset the receive FIFO. (R/W)

I2S_TX_FIFO_RESET Set this bit to reset the transmit FIFO. (R/W)

I2S_RX_RESET Set this bit to reset the receiver. (R/W)

I2S_TX_RESET Set this bit to reset the transmitter. (R/W)

8. UART Controllers

8.1 Overview

Embedded applications often require a simple method of exchanging data between devices that need minimal system resources. The Universal Asynchronous Receiver/Transmitter (UART) is one such standard that can realize a flexible full-duplex data exchange among different devices. The three UART controllers available on a chip are compatible with UART-enabled devices from various manufacturers. The UART can also carry out an IrDA (Infrared Data Exchange), or function as an RS-485 modem.

All UART controllers integrated in the ESP32 feature an identical set of registers for ease of programming and flexibility. In this documentation, these controllers are referred to as UART_n , where $n = 0, 1$, and 2 , referring to $\text{UART}0$, $\text{UART}1$, and $\text{UART}2$, respectively.

8.2 UART Features

The UART modules have the following main features:

- Programmable baud rate
- 1024 x 8-bit RAM shared by three UART transmit-FIFOs and receive-FIFOs
- Supports input baud rate self-check
- Supports 5/6/7/8 bits of data length
- Supports 1/1.5/2/3/4 STOP bits
- Supports parity bit
- Supports RS485 Protocol
- Supports IrDA Protocol
- Supports DMA to communicate data in high speed
- Supports UART wake-up
- Supports both software and hardware flow control

8.3 Functional Description

8.3.1 Introduction

UART is a character-oriented data link that can be used to achieve communication between two devices. The asynchronous mode of transmission means that it is not necessary to add clocking information to the data being sent. This, in turn, requires that the data rate, STOP bits, parity, etc., be identical at the transmitting and receiving end for the devices to communicate successfully.

A typical UART frame begins with a START bit, followed by a “character” and an optional parity bit for error detection, and it ends with a STOP condition. The UART controllers available on the ESP32 provide hardware support for multiple lengths of data and STOP bits. In addition, the controllers support both software and hardware flow control, as well as DMA, for seamless high-speed data transfer. This allows the developer to employ multiple UART ports in the system with minimal software overhead.

8.3.2 UART Architecture

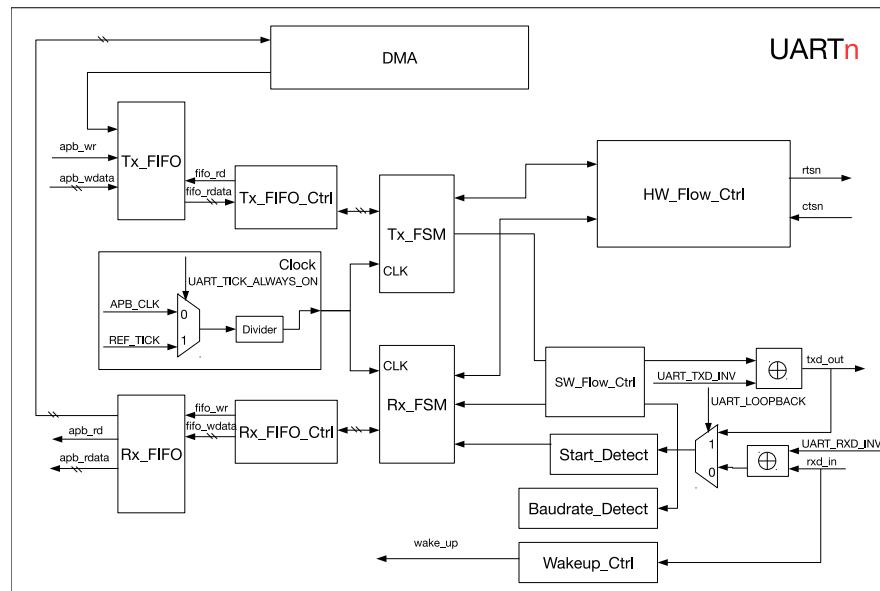

Figure 46: UART Basic Structure

Figure 46 shows the basic block diagram of the UART controller. The UART block can derive its clock from two sources: the 80-MHz APB_CLK, or the reference clock REF_TICK (please refer to Chapter [Reset and Clock](#) for more details). These two clock sources can be selected by configuring UART_TICK_REF_ALWAYS_ON.

Then, a divider in the clock path divides the selected clock source to generate clock signals that drive the UART module. UART_CLKDIV_REG contains the clock divider value in two parts — UART_CLKDIV (integral part) and UART_CLKDIV_FRAG (decimal part).

The UART controller can be further broken down into two functional blocks — the transmit block and the receive block.

The transmit block contains a transmit-FIFO buffer, which buffers data awaiting to be transmitted. Software can write Tx_FIFO via APB, and transmit data into Tx_FIFO via DMA. Tx_FIFO_Ctrl is used to control read- and write-access to the Tx_FIFO. When Tx_FIFO is not null, Tx_FSM reads data via Tx_FIFO_Ctrl, and transmits data out according to the set frame format. The outgoing bit stream can be inverted by appropriately configuring the register UART_TXD_INV.

The receive-block contains a receive-FIFO buffer, which buffers incoming data awaiting to be processed. The input bit stream, rxd_in, is fed to the UART controller. Negation of the input stream can be controlled by configuring the UART_RXD_INV register. Baudrate_Detect measures the baud rate of the input signal by measuring the minimum pulse width of the input bit stream. Start_Detect is used to detect a START bit in a frame of incoming data. After detecting the START bit, RX_FSM stores data retrieved from the received frame into Rx_FIFO through Rx_FIFO_Ctrl.

Software can read data in the Rx_FIFO through the APB. In order to free the CPU from engaging in data transfer operations, the DMA can be configured for sending or receiving data.

HW_Flow_Ctrl is able to control the data flow of rxd_in and txd_out through standard UART RTS and CTS flow control signals (rtsn_out and ctsn_in). SW_Flow_Ctrl controls the data flow by inserting special characters in the incoming and outgoing data flow. When UART is in Light-sleep mode (refer to Chapter [RTC](#)), Wakeup_Ctrl will start counting pulses in rxd_in. If the number of pulses is greater than UART_ACTIVE_THRESHOLD, a wake_up signal will be generated and sent to RTC. RTC will then wake up the UART controller.

8.3.3 UART RAM

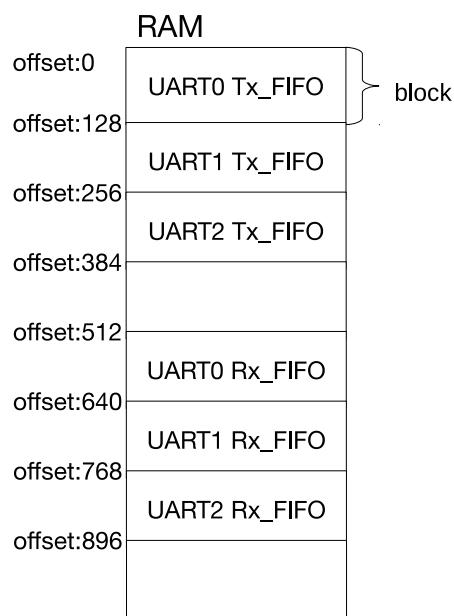

Figure 47: UART shared RAM

Three UART controllers share a 1024×8 -bit RAM space. As illustrated in Figure 47, RAM is allocated in different blocks. One block holds 128×8 -bit data. Figure 47 illustrates the default RAM allocated to Tx_FIFO and Rx_FIFO of the three UART controllers. Tx_FIFO of UART_n can be extended by setting $\text{UART}_n\text{_TX_SIZE}$, while Rx_FIFO of UART_n can be extended by setting $\text{UART}_n\text{_RX_SIZE}$.

NOTICE: Extending the FIFO space of a UART controller may take up the FIFO space of another UART controller.

If none of the UART controllers is active, setting `UART_MEM_PD`, `UART1_MEM_PD`, and `UART2_MEM_PD` can prompt the RAM to enter low-power mode.

8.3.4 Baud Rate Detection

Setting `UART_AUTOBAUD_EN` for a UART controller will enable the baud rate detection function. The `Baudrate_Detect` block shown in Figure 46 can filter glitches with a pulse width lower than `UART_GLITCH_FILT`.

In order to use the baud rate detection feature, some random data should be sent to the receiver before starting the UART communication stream. This is required so that the baud rate can be determined based on the pulse width. `UART_LOWPULSE_MIN_CNT` stores minimum low-pulse width, `UART_HIGHPULSE_MIN_CNT` stores minimum high-pulse width. By reading these two registers, software can calculate the baud rate of the transmitter.

8.3.5 UART Data Frame

Figure 48 shows the basic data frame structure. A data frame starts with a START condition and ends with a STOP condition. The START condition requires 1 bit and the STOP condition can be realized using 1/1.5/2/3/4-bit widths (as set by `UART_BIT_NUM`, `UART_DL1_EN`, and `UART_DL0_EN`). The START is low level, while the STOP is high level.

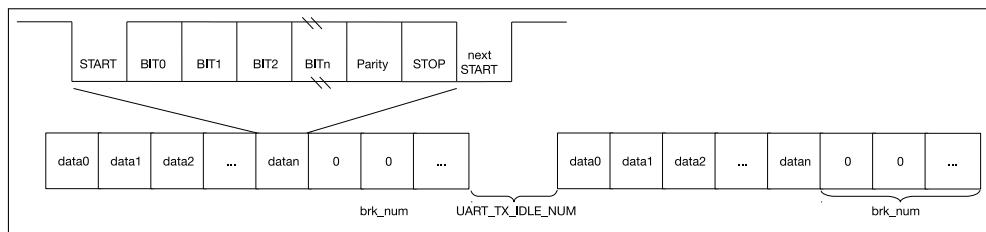

Figure 48: UART Data Frame Structure

The length of a character (BIT0 to BITn) can comprise 5 to 8 bits and can be configured by UART_BIT_NUM. When UART_PARITY_EN is set, the UART controller hardware will add the appropriate parity bit after the data. UART_PARITY is used to select odd parity or even parity. If the receiver detects an error in the input character, interrupt UART_PARITY_ERR_INT will be generated. If the receiver detects an error in the frame format, interrupt UART_FRM_ERR_INT will be generated.

Interrupt UART_TX_DONE_INT will be generated when all data in Tx_FIFO have been transmitted. When UART_TXD_BRK is set, the transmitter sends several NULL characters after the process of sending data is completed. The number of NULL characters can be configured by UART_TX_BRK_NUM. After the transmitter finishes sending all NULL characters, interrupt UART_TX_BRK_DONE_INT will be generated. The minimum interval between data frames can be configured with UART_TX_IDLE_NUM. If the idle time of a data frame is equal to, or larger than, the configured value of register UART_TX_IDLE_NUM, interrupt UART_TX_BRK_IDLE_DONE_INT will be generated.

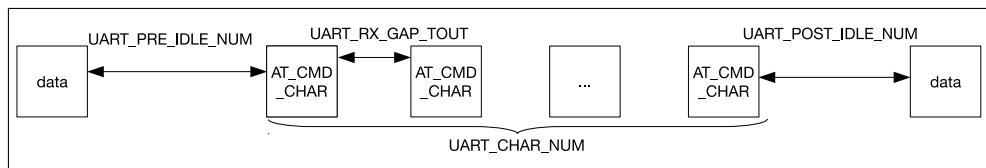

Figure 49: AT_CMD Character Format

Figure 49 shows a special AT_CMD character format. If the receiver constantly receives UART_AT_CMD_CHAR characters and these characters satisfy the following conditions, interrupt UART_AT_CMD_CHAR_DET_INT will be generated.

- Between the first UART_AT_CMD_CHAR and the last non-UART_AT_CMD_CHAR, there are at least UART_PER_IDLE_NUM APB clock cycles.
- Between every UART_AT_CMD_CHAR character there are at least UART_RX_GAP_TOUT APB clock cycles.
- The number of received UART_AT_CMD_CHAR characters must be equal to, or greater than, UART_CHAR_NUM.
- Between the last UART_AT_CMD_CHAR character received and the next non-UART_AT_CMD_CHAR, there are at least UART_POST_IDLE_NUM APB clock cycles.

8.3.6 Flow Control

UART controller supports both hardware and software flow control. Hardware flow control regulates data flow through input signal dsrn_in and output signal rtsn_out. Software flow control regulates data flow by inserting special characters in the flow of sent data and by detecting special characters in the flow of received data.

8.3.6.1 Hardware Flow Control

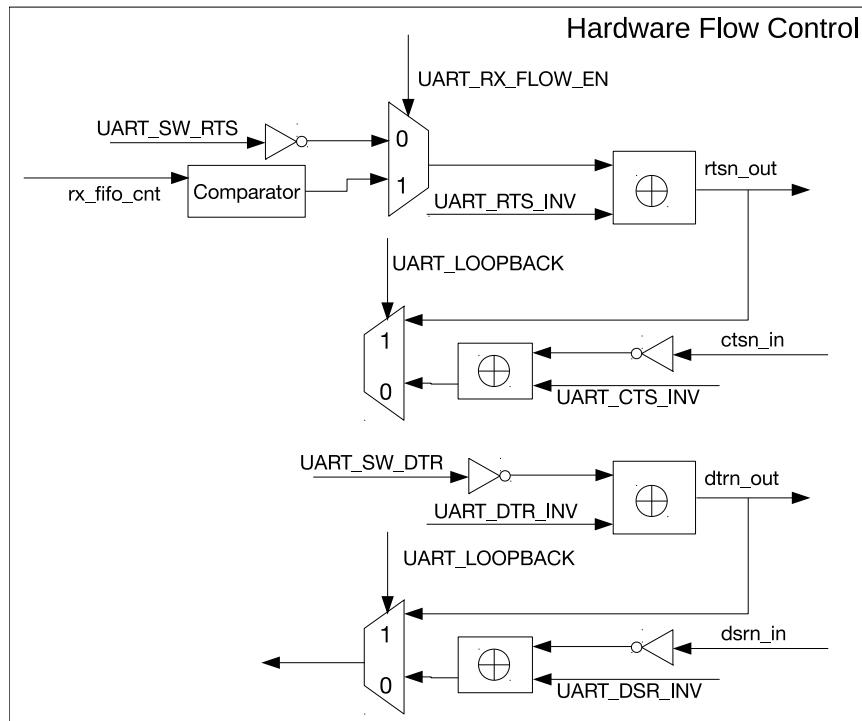

Figure 50: Hardware Flow Control

Figure 50 illustrates how the UART hardware flow control works. In hardware flow control, a high state of the output signal `rtsn_out` signifies that a data transmission is requested, while a low state of the same signal notifies the counterpart to stop data transmission until `rtsn_out` is pulled high again. There are two ways for a transmitter to realize hardware flow control:

- `UART_RX_FLOW_EN` is 0: The level of `rtsn_out` can be changed by configuring `UART_SW_RTS`.
- `UART_RX_FLOW_EN` is 1: If data in Rx_FIFO is greater than `UART_RXFIFO_FULL_THRESHOLD`, the level of `rtsn_out` will be lowered.

If the UART controller detects an edge on `ctsn_in`, it will generate interrupt `UART_CTS_CHG_INT` and will stop transmitting data, once the current data transmission is completed.

The high level of the output signal `dtrn_out` signifies that the transmitter has finished data preparation. UART controller will generate interrupt `UART_DSR_CHG_INT`, after it detects an edge on the input signal `dsrn_in`. After the software detects the above-mentioned interrupt, the input signal level of `dsrn_in` can be figured out by reading `UART_DSRN`. The software then decides whether it is able to receive data at that time or not.

Setting `UART_LOOPBACK` will enable the UART loopback detection function. In this mode, the output signal `txd_out` of UART is connected to its input signal `rxd_in`, `rtsn_out` is connected to `ctsn_in`, and `dtrn_out` is connected to `dsrn_out`. If the data transmitted corresponds to the data received, UART is able to transmit and receive data normally.

8.3.6.2 Software Flow Control

Software can force the transmitter to stop transmitting data by setting `UART_FORCE_XOFF`, as well as force the transmitter to continue sending data by setting `UART_FORCE_XON`.

UART can also control the software flow by transmitting special characters. Setting `UART_SW_FLOW_CON_EN` will enable the software flow control function. If the number of data bytes that UART has received exceeds that of the `UART_XOFF` threshold, the UART controller can send `UART_XOFF_CHAR` to instruct its counterpart to stop data transmission.

When `UART_SW_FLOW_CON_EN` is 1, software can send flow control characters at any time. When `UART_SEND_XOFF` is set, the transmitter will insert a `UART_XOFF_CHAR` and send it after the current data transmission is completed. When `UART_SEND_XON` is set, the transmitter will insert a `UART_XON_CHAR` and send it after the current data transmission is completed.

8.3.7 UART DMA

For information on the UART DMA, please refer to Chapter BUS DMA.

8.3.8 UART Interrupts

- `UART_AT_CMD_CHAR_DET_INT`: Triggered when the receiver detects the configured `at_cmd` char.
- `UART_RS485_CLASH_INT`: Triggered when a collision is detected between transmitter and receiver in RS-485 mode.
- `UART_RS485_FRM_ERR_INT`: Triggered when a data frame error is detected in RS-485.
- `UART_RS485_PARITY_ERR_INT`: Triggered when a parity error is detected in RS-485 mode.
- `UART_TX_DONE_INT`: Triggered when the transmitter has sent out all FIFO data.
- `UART_TX_BRK_IDLE_DONE_INT`: Triggered when the transmitter's idle state has been kept to a minimum after sending the last data.
- `UART_TX_BRK_DONE_INT`: Triggered when the transmitter completes sending NULL characters, after all data in transmit-FIFO are sent.
- `UART_GLITCH_DET_INT`: Triggered when the receiver detects a START bit.
- `UART_SW_XOFF_INT`: Triggered, if the receiver gets an Xon char when `uart_sw_flow_con_en` is set to 1.
- `UART_SW_XON_INT`: Triggered, if the receiver gets an Xoff char when `uart_sw_flow_con_en` is set to 1.
- `UART_RXFIFO_TOUT_INT`: Triggered when the receiver takes more time than `rx_tout_thrhd` to receive a byte.
- `UART_BRK_DET_INT`: Triggered when the receiver detects a 0 level after the STOP bit.
- `UART_CTS_CHG_INT`: Triggered when the receiver detects an edge change of the CTSn signal.
- `UART_DSR_CHG_INT`: Triggered when the receiver detects an edge change of the DSRn signal.
- `UART_RXFIFO_OVF_INT`: Triggered when the receiver gets more data than the FIFO can store.
- `UART_FRM_ERR_INT`: Triggered when the receiver detects a data frame error .
- `UART_PARITY_ERR_INT`: Triggered when the receiver detects a parity error in the data.
- `UART_TXFIFO_EMPTY_INT`: Triggered when the amount of data in the transmit-FIFO is less than what `tx_mem_cntx fifo_cnt` specifies.
- `UART_RXFIFO_FULL_INT`: Triggered when the receiver gets more data than what (`rx_flow_thrhd_h3`, `rx_flow_thrhd`) specifies.

8.3.9 UHCI Interrupts

- UHCI_SEND_A_REG_Q_INT: When using the always_send registers to send a series of short packets, this is triggered when DMA has sent a short packet.
- UHCI_SEND_S_REG_Q_INT: When using the single_send registers to send a series of short packets, this is triggered when DMA has sent a short packet.
- UHCI_OUT_TOTAL_EOF_INT: Triggered when all data have been sent.
- UHCI_OUTLINK_EOF_ERR_INT: Triggered when there are some errors in EOF in the outlink descriptor.
- UHCI_IN_DSCR_EMPTY_INT: Triggered when there are not enough inlinks for DMA.
- UHCI_OUT_DSCR_ERR_INT: Triggered when there are some errors in the inlink descriptor.
- UHCI_IN_DSCR_ERR_INT: Triggered when there are some errors in the outlink descriptor.
- UHCI_OUT_EOF_INT: Triggered when the current descriptor's EOF bit is 1.
- UHCI_OUT_DONE_INT: Triggered when an outlink descriptor is completed.
- UHCI_IN_ERR_EOF_INT: Triggered when there are some errors in EOF in the inlink descriptor.
- UHCI_IN_SUC_EOF_INT: Triggered when a data packet has been received.
- UHCI_IN_DONE_INT: Triggered when an inlink descriptor has been completed.
- UHCI_TX_HUNG_INT: Triggered when DMA takes much time to read data from RAM.
- UHCI_RX_HUNG_INT: Triggered when DMA takes much time to receive data .
- UHCI_TX_START_INT: Triggered when DMA detects a separator char.
- UHCI_RX_START_INT: Triggered when a separator char has been sent.

UART_RXD This bit represents the level of the internal UART RxD signal. (RO)

UART_RTSN This bit corresponds to the level of the internal UART CTS signal. (RO)

UART_DTRN This bit corresponds to the level of the internal UAR DSR signal. (RO)

UART_ST_UTX_OUT This register stores the state of the transmitter's finite state machine. 0: TX_IDLE; 1: TX_STRT; 2: TX_DAT0; 3: TX_DAT1; 4: TX_DAT2; 5: TX_DAT3; 6: TX_DAT4; 7: TX_DAT5; 8: TX_DAT6; 9: TX_DAT7; 10: TX_PRTY; 11: TX_STP1; 12: TX_STP2; 13: TX_DL0; 14: TX_DL1. (RO)

UART_TXFIFO_CNT (tx_mem_cnt, txfifo_cnt) stores the number of bytes of valid data in transmit FIFO. tx_mem_cnt stores the three most significant bits, txfifo_cnt stores the eight least significant bits. (RO)

UART_RXD This bit corresponds to the level of the internal UART RxD signal. (RO)

UART_CTSN This bit corresponds to the level of the internal UART CTS signal. (RO)

UART_DSRN This bit corresponds to the level of the internal UAR DSR signal. (RO)

UART_ST_URX_OUT This register stores the value of the receiver's finite state machine. 0: RX_IDLE; 1: RX_STRT; 2: RX_DAT0; 3: RX_DAT1; 4: RX_DAT2; 5: RX_DAT3; 6: RX_DAT4; 7: RX_DAT5; 8: RX_DAT6; 9: RX_DAT7; 10: RX_PRTY; 11: RX_STP1; 12: RX_STP2; 13: RX_DL1. (RO)

UART_RXFIFO_CNT (rx_mem_cnt, rxfifo_cnt) stores the number of bytes of valid data in the receive FIFO. rx_mem_cnt register stores the three most significant bits, rxfifo_cnt stores the eight least significant bits. (RO)

UART_TICK_REF_ALWAYS_ON This register is used to select the clock; 1: APB clock; 0: REF_TICK. (R/W)

UART_DTR_INV Set this bit to invert the level of the UART DTR signal. (R/W)

UART_RTS_INV Set this bit to invert the level of the UART RTS signal. (R/W)

UART_TXD_INV Set this bit to invert the level of the UART TxD signal. (R/W)

UART_DSR_INV Set this bit to invert the level of the UART DSR signal. (R/W)

UART_CTS_INV Set this bit to invert the level of the UART CTS signal. (R/W)

UART_RXD_INV Set this bit to invert the level of the UART Rxd signal. (R/W)

UART_TXFIFO_RST Set this bit to reset the UART transmit-FIFO. (R/W)

UART_RXFIFO_RST Set this bit to reset the UART receive-FIFO. (R/W)

UART_IRDA_EN Set this bit to enable the IrDA protocol. (R/W)

UART_TX_FLOW_EN Set this bit to enable the flow control function for the transmitter. (R/W)

UART_LOOPBACK Set this bit to enable the UART loopback test mode. (R/W)

UART_IRDA_RX_INV Set this bit to invert the level of the IrDA receiver. (R/W)

UART_IRDA_TX_INV Set this bit to invert the level of the IrDA transmitter. (R/W)

UART_IRDA_WCTL 1: The IrDA transmitter's 11th bit is the same as its 10th bit; 0: set IrDA transmitter's 11th bit to 0. (R/W)

UART_IRDA_TX_EN This is the start enable bit of the IrDA transmitter. (R/W)

UART_IRDA_DPLX Set this bit to enable the IrDA loopback mode. (R/W)

UART_TXD_BRK Set this bit to enable the transmitter to send NULL, when the process of sending data is completed. (R/W)

UART_SW_DTR This register is used to configure the software DTR signal used in software flow control. (R/W)

UART_SW_RTS This register is used to configure the software RTS signal used in software flow control. (R/W)

UART_STOP_BIT_NUM This register is used to set the length of the stop bit; 1: 1 bit, 2: 1.5 bits. (R/W)

UART_BIT_NUM This register is used to set the length of data; 0: 5 bits, 1: 6 bits, 2: 7 bits, 3: 8 bits. (R/W)

UART_PARITY_EN Set this bit to enable the UART parity check. (R/W)

UART_PARITY This register is used to configure the parity check mode; 0: even, 1: odd. (R/W)

Register 8.10: UART_CONF1_REG (0x24)

UART_RX_TOUT_EN This is the enable bit for the UART receive-timeout function. (R/W)

UART_RX_TOUT_THRESHOLD This register is used to configure the UART receiver's timeout value when receiving a byte. (R/W)

UART_RX_FLOW_EN This is the flow enable bit of the UART receiver; 1: choose software flow control by configuring the sw_rts signal; 0: disable software flow control. (R/W)

UART_RX_FLOW_THRESHOLD When the receiver gets more data than its threshold value, the receiver produces a signal that tells the transmitter to stop transferring data. The threshold value is (rx_flow_thrhd_h3, rx_flow_thrhd). (R/W)

UART_TXFIFO_EMPTY_THRESHOLD When the data amount in transmit-FIFO is less than its threshold value, it will produce a TXFIFO_EMPTY_INT_RAW interrupt. The threshold value is (tx_mem_empty_thrhd, txfifo_empty_thrhd). (R/W)

UART_RXFIFO_FULL_THRESHOLD When the receiver gets more data than its threshold value, the receiver will produce an RXFIFO_FULL_INT_RAW interrupt. The threshold value is (rx_flow_thrhd_h3, rxfifo_full_thrhd). (R/W)

UART_XOFF_CHAR	UART_XON_CHAR	UART_XOFF_THRESHOLD

UART_XOFF_CHAR This register stores the Xoff flow control char. (R/W)

UART_XON_CHAR This register stores the Xon flow control char. (R/W)

UART_XOFF_THRESHOLD When the data amount in receive-FIFO is less than what this register indicates, it will send an Xon char, with uart_sw_flow_con_en set to 1. (R/W)

UART_XON_THRESHOLD When the data amount in receive-FIFO is more than what this register indicates, it will send an Xoff char, with uart_sw_flow_con_en set to 1. (R/W)

Register 8.17: UART_IDLE_CONF_REG (0x40)

The diagram shows the bit field layout of the register. It consists of four columns of bits, each labeled with its bit number at the top. The first column (bits 31-28) is labeled '(reserved)'. The second column (bits 27-20) is labeled 'UART_TX_BRK_NUM'. The third column (bits 19-10) is labeled 'UART_RX_IDLE_NUM'. The fourth column (bits 9-0) is labeled 'UART_RX_IDLE_THRHD'. The first three columns have values 0x00A, 0x100, and 0x100 respectively. The fourth column has a 'Reset' label.

31	28	27	20	19	10	9	0
0	0	0	0	0x00A	0x100	0x100	Reset

UART_TX_BRK_NUM This register is used to configure the number of zeros (0) sent, after the process of sending data is completed. It is active when txd_brk is set to 1. (R/W)

UART_RX_IDLE_NUM This register is used to configure the duration between transfers. (R/W)

UART_RX_IDLE_THRHD When the receiver takes more time to receive Byte data than what this register indicates, it will produce a frame-end signal. (R/W)

Register 8.18: UART_RS485_CONF_REG (0x44)

The diagram shows the bit field layout of the register. It consists of four columns of bits, each labeled with its bit number at the top. The first column (bits 31-28) is labeled '(reserved)'. The second column (bits 27-20) is labeled 'UART_RS485_TX_DLY_NUM'. The third column (bits 19-10) is labeled 'UART_RS485_RX_DLY_NUM'. The fourth column (bits 9-0) is labeled 'UART_RS485_RXBY_TX_EN', 'UART_RS485RXBY_RX_EN', 'UART_RS485TX_RX_EN', 'UART_DL1_EN', 'UART_DL0_EN', and 'UART_RS485_EN'. The first three columns have values 0x00000000. The fourth column has a 'Reset' label.

UART_RS485_TX_DLY_NUM This register is used to delay the transmitter's internal data signal. (R/W)

UART_RS485_RX_DLY_NUM This register is used to delay the receiver's internal data signal. (R/W)

UART_RS485RXBY_TX_EN 1: enable the RS-485 transmitter to send data, when the RS-485 receiver line is busy; 0: the RS-485 transmitter should not send data, when its receiver is busy. (R/W)

UART_RS485TX_RX_EN Set this bit to enable the transmitter's output signal loop back to the receiver's input signal. (R/W)

UART_DL1_EN Set this bit to delay the STOP bit by 1 bit. (R/W)

UART_DL0_EN Set this bit to delay the STOP bit by 1 bit. (R/W)

UART_RS485_EN Set this bit to choose the RS-485 mode. (R/W)

9. LED_PWM

9.1 Introduction

The LED_PWM controller is primarily designed to control the intensity of LEDs, although it can be used to generate PWM signals for other purposes as well. It has 16 channels which can generate independent waveforms that can be used to drive RGB LED devices. For maximum flexibility, the high-speed as well as the low-speed channels can be driven from one of four high-speed/low-speed timers. The PWM controller also has the ability to automatically increase or decrease the duty cycle gradually, allowing for fades without any processor interference. To increase resolution, the LED_PWM controller is also able to dither between two values, when a fractional PWM value is configured.

The LED_PWM controller has eight high-speed and eight low-speed PWM generators. In this document, they will be referred to as `hsch n` and `lsch n` , respectively. These channels can be driven from four timers which will be indicated by `h_timer x` and `l_timer x` .

9.2 Functional Description

9.2.1 Architecture

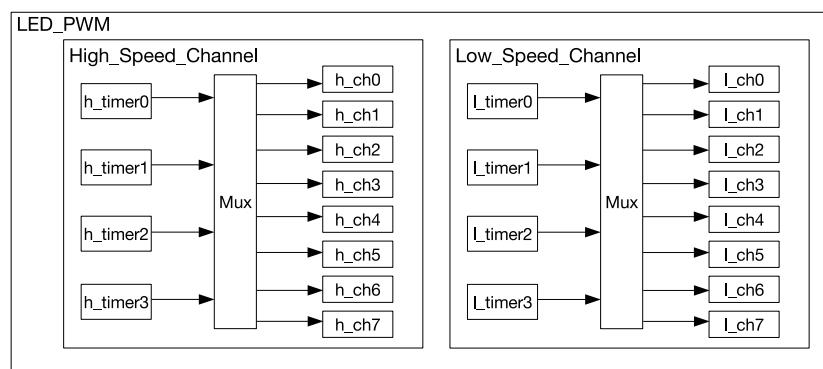

Figure 51: LED_PWM Architecture

Figure 51 shows the architecture of the LED_PWM controller. As can be seen in the figure, the LED_PWM controller contains eight high-speed and eight low-speed channels. There are four high-speed clock modules for the high-speed channels, from which one `h_timer x` can be selected. There are also four low-speed clock modules for the low-speed channels, from which one `l_timer x` can be selected.

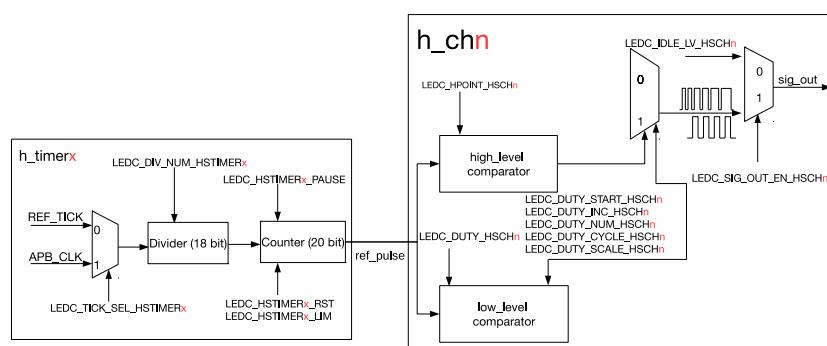

Figure 52: LED_PWM High-speed Channel Diagram

Figure 52 illustrates a PWM channel with its selected timer; in this instance a high-speed channel and associated high-speed timer.

9.2.2 Timers

A high-speed timer consists of a multiplexer to select one of two clock sources: either REF_TICK or APB_CLK. For more information on the clock sources, please see Chapter [Reset And Clock](#). The input clock is divided down by a divider first. The division factor is specified by `LEDC_DIV_NUM_HSTIMERx` which contains a fixed point number: the highest 10 bits represent the integer portion, while the lowest eight bits contain the fractional portion.

The divided clock signal is then fed into a 20-bit counter. This counter will count up to the value specified in `LEDC_HSTIMERx_LIM`. An overflow interrupt will be generated once the counting value reaches this limit, at which point the counter restarts counting from zero. It is also possible to reset, suspend, and read the values of the counter by software.

The output signal of the timer is the 20-bit value generated by the counter. The cycle period of this signal defines the frequency of the signals of any PWM channels connected to this timer. This frequency depends on both the division factor of the divider, as well as the range of the counter:

$$f_{\text{sig_out}} = \frac{f_{\text{REF_TICK}} \cdot (\text{!LEDC_TICK_SEL_HSTIMER}x) + f_{\text{APB_CLK}} \cdot \text{LEDC_TICK_SEL_HSTIMER}x}{\text{LEDC_DIV_NUM_HSTIMER}x \cdot 2^{\text{LEDC_HSTIMER}x\text{_LIM}}}$$

The low-speed timers `l_timerx` on the low-speed channel differ from the high-speed timers `h_timerx` in two aspects:

1. Where the high-speed timer clock source can be clocked from REF_TICK or APB_CLK, the low speed timers are sourced from either REF_TICK or SLOW_CLOCK. The SLOW_CLOCK source can be either APB_CLK (80 MHz) or 8 MHz, and can be selected using `LEDC_APB_CLK_SEL`.
2. The high-speed counter and divider are glitch-free, which means that if the software modifies the maximum counter or divisor value, the update will come into effect after the next overflow interrupt. In contrast, the low-speed counter and divider will update these values only when `LEDC_LSTIMERx_PARA_UP` is set.

9.2.3 Channels

A channel takes the 20-bit value from the counter of the selected high-speed timer and compares it to a set of two values in order to set the channel output. The first value it is compared to is the content of `LEDC_HPOINT_HSCHn`; if these two match, the output will be latched high. The second value is the sum of `LEDC_HPOINT_HSCHn` and `LEDC_DUTY_HSCHn[24..4]`. When this value is reached, the output is latched low. By using these two values, the relative phase and the duty cycle of the PWM output can be set. Figure 53 illustrates this.

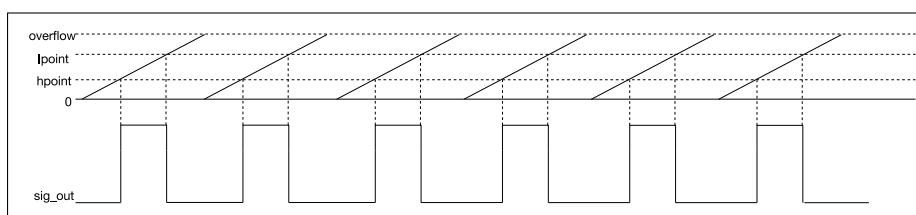

Figure 53: LED PWM Output Signal Diagram

`LEDC_DUTY_HSCH n` is a fixed-point register with four fractional bits. As mentioned before, when `LEDC_DUTY_HSCH n [24..4]` is used in the PWM calculation directly, `LEDC_DUTY_HSCH n [3..0]` can be used to dither the output. If this value is non-zero, with a statistical chance of `LEDC_DUTY_HSCH n [3..0]/16`, the actual PWM pulse will be one cycle longer. This effectively increases the resolution of the PWM generator to 24 bits, but at the cost of a slight jitter in the duty cycle.

The channels also have the ability to automatically fade from one duty cycle value to another. This feature is enabled by setting `LEDC_DUTY_START_HSCH n` . When this bit is set, the PWM controller will automatically increment or decrement the value in `LEDC_DUTY_HSCH n` , depending on whether the bit `LEDC_DUTY_INC_HSCH n` is set or cleared, respectively. The speed the duty cycle changes is defined as such: every time the `LEDC_DUTY_CYCLE_HSCH n` cycles, the content of `LEDC_DUTY_SCALE_HSCH n` is added to or subtracted from `LEDC_DUTY_HSCH n [24..4]`. The length of the fade can be limited by setting `LEDC_DUTY_NUM_HSCH n` : the fade will only last that number of cycles before finishing. A finished fade also generates an interrupt.

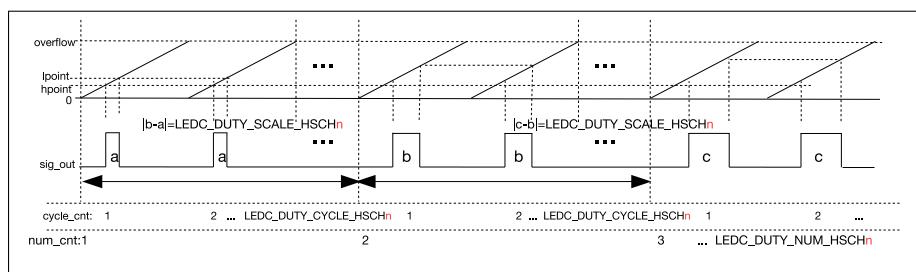

Figure 54: Output Signal Diagram of Gradient Duty Cycle

Figure 54 is an illustration of this. In this configuration, `LEDC_DUTY_NUM_HSCH n _R` increases by `LEDC_DUTY_SCALE_HSCH n` for every `LEDC_DUTY_CYCLE_HSCH n` clock cycles, which is reflected in the duty cycle of the output signal.

9.2.4 Interrupts

- `LEDC_DUTY_CHNG_END_LSCH n _INT`: Triggered when a fade on a low-speed channel has finished.
- `LEDC_DUTY_CHNG_END_HSCH n _INT`: Triggered when a fade on a high-speed channel has finished.
- `LEDC_HS_TIMER x _OVF_INT`: Triggered when a high-speed timer has reached its maximum counter value.
- `LEDC_LS_TIMER x _OVF_INT`: Triggered when a low-speed timer has reached its maximum counter value.

9.4 Registers

Register 9.1: LEDC_HSCH n _CONF0_REG (n : 0-7) (0x1C+0x10* n)

The diagram shows the bit field layout of Register 9.1. It consists of a 32-bit register with the following bit descriptions:

- Bit 31:** (reserved)
- Bit 4:** LEDC_IDLE_LV_HSCH n (R/W)
- Bit 3:** LEDC_SIG_OUT_EN_HSCH n (R/W)
- Bit 2:** LEDC_TIMER_SEL_HSCH n (R/W)
- Bit 1:** (reserved)
- Bit 0:** Reset (R/W)

31	4	3	2	1	0		
0x00000000					0	0	Reset

LEDC_IDLE_LV_HSCH n This bit is used to control the output value when high-speed channel n is inactive. (R/W)

LEDC_SIG_OUT_EN_HSCH n This is the output enable control bit for high-speed channel n . (R/W)

LEDC_TIMER_SEL_HSCH n There are four high-speed timers. These two bits are used to select one of them for high-speed channel n : (R/W)

- 0: select hstimer0;
- 1: select hstimer1;
- 2: select hstimer2;
- 3: select hstimer3.

Register 9.2: LEDC_HSCH n _HPOINT_REG (n : 0-7) (0x20+0x10* n)

The diagram shows the bit field layout of Register 9.2. It consists of a 32-bit register with the following bit descriptions:

- Bit 31:** (reserved)
- Bit 20:** (reserved)
- Bit 19:** LEDC_HPOINT_HSCH n (R/W)
- Bit 0:** (reserved)

31	20	19	0
0x0000		0x000000	Reset

LEDC_HPOINT_HSCH n The output value changes to high when htimer x (x =[0,3]), selected by high-speed channel n , has reached reg_hpoint_hschn[19:0]. (R/W)

Register 9.3: LEDC_HSCH n _DUTY_REG (n : 0-7) (0x24+0x10* n)

31	25	24	0
0x00		0x000000	Reset

LEDC_DUTY_HSCH n The register is used to control output duty. When hstimerx(x=[0,3]), selected by high-speed channel n , has reached reg_lpoint_hschn, the output signal changes to low. (R/W)
 $\text{reg_lpoint_hschn} = (\text{reg_hpoint_hschn}[19:0] + \text{reg_duty_hschn}[24:4])$ (1)
 $\text{reg_lpoint_hschn} = (\text{reg_hpoint_hschn}[19:0] + \text{reg_duty_hschn}[24:4] + 1)$ (2)
See the [Functional Description](#) for more information on when (1) or (2) is chosen.

Register 9.4: LEDC_HSCH n _CONF1_REG (n : 0-7) (0x28+0x10* n)

31	30	29	20	19	10	9	0
0	1	0x000		0x000		0x000	Reset

LEDC_DUTY_START_HSCH n When REG_DUTY_NUM_HSCH n , REG_DUTY_CYCLE_HSCH n and REG_DUTY_SCALE_HSCH n has been configured, these register will not take effect until REG_DUTY_START_HSCH n is set. This bit is automatically cleared by hardware. (R/W)

LEDC_DUTY_INC_HSCH n This register is used to increase or decrease the duty of output signal for high-speed channel n . (R/W)

LEDC_DUTY_NUM_HSCH n This register is used to control the number of times the duty cycle is increased or decreased for high-speed channel n . (R/W)

LEDC_DUTY_CYCLE_HSCH n This register is used to increase or decrease the duty cycle every time REG_DUTY_CYCLE_HSCH n cycles for high-speed channel n . (R/W)

LEDC_DUTY_SCALE_HSCH n This register is used to increase or decrease the step scale for high-speed channel n . (R/W)

Register 9.5: LEDC_HSCH n _DUTY_R_REG (n : 0-7) (0x2C+0x10* n)

The diagram shows the bit field layout of the LEDC_HSCH n _DUTY_R_REG register. It consists of two rows. The top row has three columns: bit 31 (labeled '(reserved)'), bit 25 (labeled 'LEDC_DUTY_HSCH n _R'), and bit 0 (labeled '0'). The bottom row has two columns: bit 0x000 (labeled '0x000000') and a 'Reset' button.

10. Remote Controller Peripheral

10.1 Introduction

The RMT (Remote Control) module is primarily designed to send and receive infrared remote control signals that use on-off-keying of a carrier frequency, but due to its design it can be used to generate various types of signals. An RMT transmitter does this by reading consecutive duration values from the built-in RAM block, optionally modulating it with a carrier wave. A receiver will inspect its input signal, optionally filtering it, and will place the lengths of time the signal is active and inactive in the RAM block.

The RMT module has eight channels, numbered zero to seven; registers, signals and blocks that are duplicated in each channel are indicated by an *n* which is used as a placeholder for the channel number.

10.2 Functional Description

10.2.1 RMT Architecture

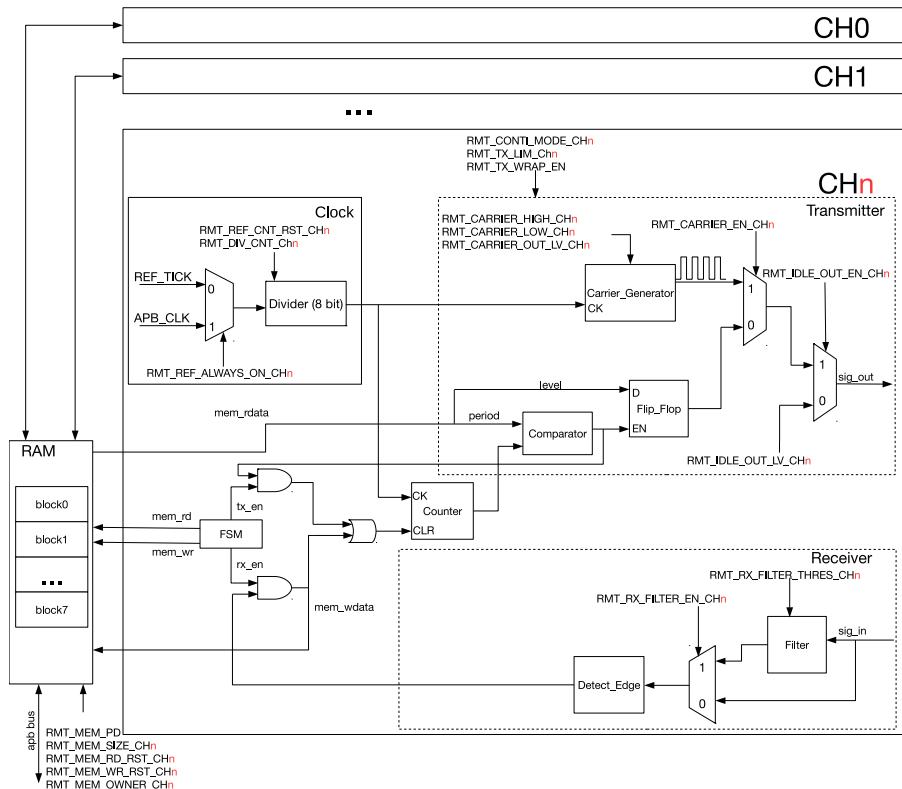

Figure 55: RMT Architecture

The RMT module contains eight channels; each channel has a transmitter and receiver, of which one can be active per channel. The eight channels share a 512x32-bit RAM block which can be read and written by the processor cores over the APB bus, read by the transmitters, and written by the receivers. The transmitted signal can optionally be modulated by a carrier wave. Each channel is clocked by a divided-down signal derived from either the APB bus clock or REF_TICK.

10.2.2 RMT RAM

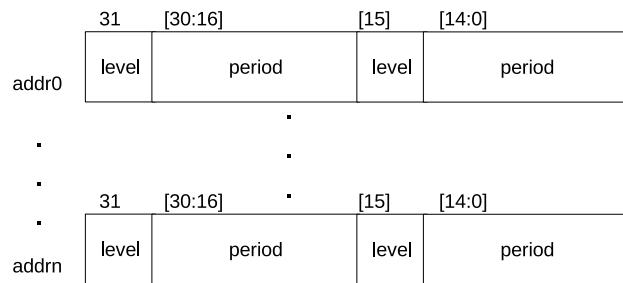

Figure 56: Data Structure

The data structure in RAM is shown in Figure 56. Each 32-bit value contains two 16-bit entries, containing two fields each: "level" indicates whether a high-/low-level value was received or is going to be sent, and "period" is the duration (in channel clock periods) for which the level lasts. A zero period is interpreted as an end-marker: the transmitter will stop transmitting once it has read this, and the receiver will write this, once it has detected that the signal it received has gone idle.

Normally, only one block of 64x32-bit worth of data can be sent or received. If the data size is larger than this block size, blocks can either be extended or the channel can be configured for wraparound mode.

The RMT RAM can be accessed via APB bus. The initial address is RMT base address + 0x800. The RAM block is divided into eight 64x32-bit blocks. By default, each channel uses one block (block zero for channel zero, block one for channel one, and so on). Users can extend the memory for a specific channel by configuring `RMT_MEM_SIZE_CH n` register; setting this to >1 will prompt the channel to use the memory of subsequent channels as well. The RAM address range for channel n is `start_addr_CH n` to `end_addr_CH n` , which are defined by:

$$\text{start_addr_ch}n = \text{RMT base address} + 0x800 + 64 * 4 * n, \text{ and}$$

$$\text{end_addr_ch}n = \text{RMT base address} + 0x800 + 64 * 4 * n + 64 * 4 * \text{RMT_MEM_SIZE_CH}n \bmod 512 * 4$$

To protect a receiver from overwriting the blocks a transmitter is about to transmit, `RMT_MEM_OWNER_CH n` can be configured to assign the owner, i.e. transmitter or receiver, of channel n 's RAM block. If this ownership is violated, the `RMT_CH n _ERR` interrupt will be generated.

10.2.3 Clock

The main clock for a channel is generated by taking either the 80 MHz APB clock or REF_TICK (usually 1MHz), according to the state of `RMT_REF_ALWAYS_ON_CH n` . (For more information on the clock sources, please see Chapter [Reset And Clock](#).) Then, the aforementioned state gets scaled down using a configurable 8-bit divider to create the channel clock which is used by both the carrier wave generator and the counter. The divider value can be set by configuring `RMT_DIV_CNT_CH n` .

10.2.4 Transmitter

When the `RMT_TX_START_CH n` register is 1, the transmitter of channel n will start reading data from RAM and sending it. The transmitter will receive a 32-bits value each time it reads from RAM. Of these 32 bits, the low 16-bit entry is sent first and the high entry second.

To transmit more data than can be fitted in the channel's RAM, wraparound mode can be enabled. In this mode, when the transmitter has reached the last entry in the channel's memory, it will loop back to the first byte. To use this mechanism to send more data than can be fitted in the channel's RAM, fill the RAM with the initial events and

set RMT_CH n _TX_LIM_REG to cause an RMT_CH n _TX_THR_EVENT_INT interrupt before the wraparound happens. Then, when the interrupt happens, the already sent data should be replaced by subsequent events: when the wraparound happens the transmitter will seamlessly continue sending the new events.

With or without wraparound mode enabled, transmission ends when an entry with zero length is encountered. When this happens, the transmitter will generate a RMT_CH n _TX_END_INT interrupt, and return to the idle state. When a transmitter is in the idle state, users can configure RMT_IDLE_OUT_EN_CH n and RMT_IDLE_OUT_LV_CH n to control the transmitter output manually.

The output of the transmitter can be modulated using a carrier wave by setting RMT_CARRIER_EN_CH n . The carrier frequency and duty cycle can be configured by adjusting its high and low durations in channel clock cycles, in RMT_CARRIER_HIGH_CH n and RMT_CARRIER_LOW_CH n .

10.2.5 Receiver

When RMT_RX_EN_CH n is set to 1, the receiver in channel n becomes active, measuring the duration between input signal edges. These will be written as period/level value pairs to the channel RAM in the same fashion as the transmitter sends them. Receiving ends when the receiver detects no change in signal level for more than RMT_IDLE_THRESH_CH n channel clock ticks; the receiver will write a final entry with 0 period, generate an RMT_CH n _RX_END_INT_RAW interrupt, and return to the idle state.

The receiver has an input signal filter which can be configured using RMT_RX_FILTER_EN_CH n : The filter will remove pulses with a length of less than RMT_RX_FILTER_THRESH_CH n in APB clock periods.

When the RMT module is inactive, the RAM can be put into low-power mode by setting the RMT_MEM_PD register to 1.

10.2.6 Interrupts

- RMT_CH n _TX_THR_EVENT_INT: Triggered when the number of events the transmitter has sent matches the contents of the RMT_CH n _TX_LIM_REG register.
- RMT_CH n _TX_END_INT: Triggered when the transmitter has finished transmitting the signal.
- RMT_CH n _RX_END_INT: Triggered when the receiver has finished receiving a signal.

RMT_MEM_PD This bit is used to power down the entire RMT RAM block. (It only exists in RMT_CH0CONF0). 1: power down memory; 0: power up memory. (R/W)

RMT_CARRIER_OUT_LV_CH n This bit is used for configuration when the carrier wave is being transmitted. Transmit on low output level with 1, and transmit on high output level with 0. (R/W)

RMT_CARRIER_EN_CH n This is the carrier modulation enable control bit for channel n . Carrier modulation is enabled with 1, while carrier modulation is disabled with 0. (R/W)

RMT_MEM_SIZE_CH n This register is used to configure the amount of memory blocks allocated to channel n (R/W)

RMT_IDLE_THRES_CH n In receive mode, when no edge is detected on the input signal for longer than reg_idle_thres_ch n channel clock cycles, the receive process is finished. (R/W)

RMT_DIV_CNT_CH n This register is used to set the divider for the channel clock of channel n . (R/W)

Register 10.2: RMT_CH n CONF1_REG (n : 0-7) (0x005c+8* n)

The diagram shows the bit field layout for the RMT_CH n CONF1_REG register. Bits 31 to 16 are labeled (reserved). Bits 15 to 0 are labeled as follows: RMT_IDLE_OUT_EN_CH n , RMT_IDLE_OUT_LV_CH n , RMT_REF_ALWAYS_ON_CH n , RMT_REF_CNT_RST_CH n , RMT_RX_FILTER_THRES_CH n , RMT_RX_FILTER_EN_CH n , RMT_TX_CONTI_MODE_CH n , RMT_MEM_OWNER_CH n , (reserved), RMT_MEM_RD_RST_CH n , RMT_MEM_WR_RST_CH n , RMT_RX_EN_CH n , and RMT_TX_START_CH n . RMT_IDLE_OUT_EN_CH n This is the output enable control bit for channel n in IDLE state. (R/W)

RMT_IDLE_OUT_LV_CH n This bit configures the output signals level for channel n in IDLE state. (R/W)

RMT_REF_ALWAYS_ON_CH n This bit is used to select the channel's base clock. 1:clk_apb; 0:clk_ref. (R/W)

RMT_REF_CNT_RST_CH n Setting this bit resets the clock divider of channel n . (R/W)

RMT_RX_FILTER_THRES_CH n In receive mode, channel n ignores input pulse when the pulse width is smaller than this value in APB clock periods. (R/W)

RMT_RX_FILTER_EN_CH n This is the receive filter enable bit for channel n . (R/W)

RMT_TX_CONTI_MODE_CH n If this bit is set, instead of going to idle when the transmission ends, the transmitter will restart transmission. This results in a repeating output signal. (R/W)

RMT_MEM_OWNER_CH n This bit marks channel n 's RAM block ownership. Number 1 stands for the receiver using the RAM, while 0 stands for the transmitter using the RAM. (R/W)

RMT_MEM_RD_RST_CH n Set this bit to reset read RAM address for channel n by transmitter access. (R/W)

RMT_MEM_WR_RST_CH n Set this bit to reset write RAM address for channel n by receiver access. (R/W)

RMT_RX_EN_CH n Set this bit to enable receiving data on channel n . (R/W)

RMT_TX_START_CH n Set this bit to start sending data on channel n . (R/W)

Register 10.7: RMT_CH n CARRIER_DUTY_REG (n : 0-7) (0x00cc+4* n)

The register is divided into two main fields: RMT_CARRIER_HIGH_CH n (left) and RMT_CARRIER_LOW_CH n (right). Both fields are 16-bit registers with a width of 16 bits (bits 15 to 0). The left field contains the value 0x000040, and the right field also contains the value 0x000040. A 'Reset' label is positioned at the far right of the right field.

31	16	15	0
0x000040		0x000040	Reset

RMT_CARRIER_HIGH_CH n This field is used to configure the carrier wave high-level duration (in channel clock periods) for channel n . (R/W)

RMT_CARRIER_LOW_CH n This field is used to configure the carrier wave low-level duration (in channel clock periods) for channel n . (R/W)

Register 10.8: RMT_CH n _TX_LIM_REG (n : 0-7) (0x00ec+4* n)

The register consists of a 16-bit field labeled '(reserved)' (bits 31 to 9) and a 8-bit field labeled RMT_TX_LIM_CH n (bits 8 to 0). The '(reserved)' field contains the value 0x0000000, and the RMT_TX_LIM_CH n field contains the value 0x080. A 'Reset' label is positioned at the far right of the RMT_TX_LIM_CH n field.

0x0000000		0x080	Reset

RMT_TX_LIM_CH n When channel n sends more entries than specified here, it produces a TX_THR_EVENT interrupt. (R/W)

Register 10.9: RMT_APB_CONF_REG (0x00f0)

The register consists of a 16-bit field labeled '(reserved)' (bits 31 to 2) and a 1-bit field labeled RMT_MEM_TX_WRAP_EN (bit 1). The '(reserved)' field contains the value 0x00000000, and the RMT_MEM_TX_WRAP_EN field contains the value 0. A 'Reset' label is positioned at the far right of the RMT_MEM_TX_WRAP_EN field.

31	2	1	0
0x00000000		0	Reset

RMT_MEM_TX_WRAP_EN bit enables wraparound mode: when the transmitter of a channel has reached the end of its memory block, it will resume sending at the start of its memory region. (R/W)

11. PULSE_CNT

11.1 Introduction

The pulse counter module is designed to count the number of rising and/or falling edges of an input signal. Each pulse counter unit has a 16-bit signed counter register and two channels that can be configured to either increment or decrement the counter. Each channel has a signal input that accepts signal edges to be detected, as well as a control input that can be used to enable or disable the signal input. The inputs have optional filters that can be used to discard unwanted glitches in the signal.

The pulse counter has eight independent units, referred to as PULSE_CNT_Us.

11.2 Functional Description

11.2.1 Architecture

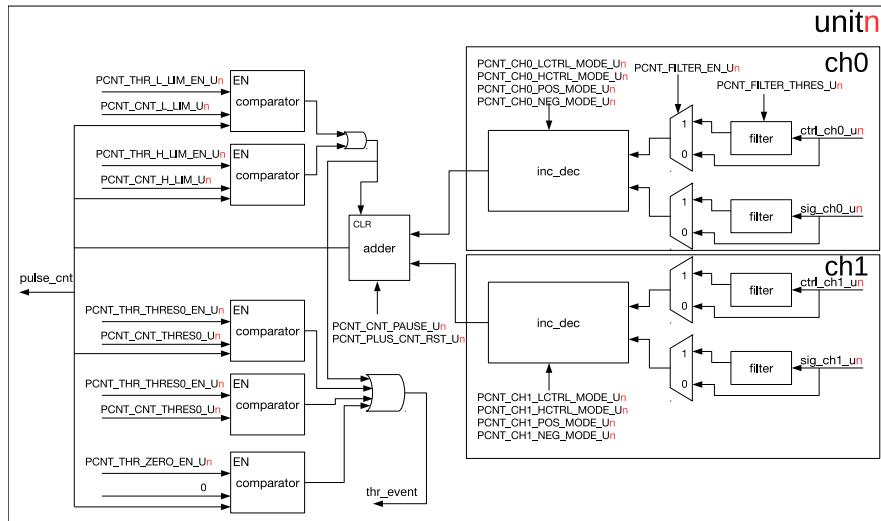

Figure 57: PULSE_CNT Architecture

The architecture of a pulse counter unit is illustrated in Figure 57. Each unit has two channels: ch0 and ch1, which are functionally equivalent. Each channel has a signal input, as well as a control input, which can both be connected to I/O pads. The counting behavior on both the positive and negative edge can be configured separately to increase, decrease, or do nothing to the counter value. Separately, for both control signal levels, the hardware can be configured to modify the edge action: invert it, disable it, or do nothing. The counter itself is a 16-bit signed up/down counter. Its value can be read by software directly, but is also monitored by a set of comparators which can trigger an interrupt.

11.2.2 Counter Channel Inputs

As stated before, the two inputs of a channel can affect the pulse counter in various ways. The specifics of this behaviour are set by LCTRL_MODE and HCTRL_MODE in this case when the control signal is low or high, respectively, and POS_MODE and NEG_MODE for positive and negative edges of the input signal. Setting POS_MODE and NEG_MODE to 1 will increase the counter when an edge is detected, setting them to 2 will decrease the counter and setting at any other value will neutralize the effect of the edge on the counter. LCTR_MODE and HCTR_MODE modify this behaviour, when the control input has the corresponding low or high

value: 0 does not modify the NEG_MODE and POS_MODE behaviour, 1 inverts it (setting POS_MODE/NEG_MODE to increase the counter should now decrease the counter and vice versa) and any other value disables counter effects for that signal level.

To summarize, a few examples have been considered. In this table, the effect on the counter for a rising edge is shown for both a low and a high control signal, as well as various other configuration options. For clarity, a short description in brackets is added after the values. Note: x denotes 'do not care'.

POS_MODE	LCTRL_MODE	HCTRL_MODE	sig I→h when ctrl=0	sig I→h when ctrl=1
1 (inc)	0 (-)	0 (-)	Inc ctr	Inc ctr
2 (dec)	0 (-)	0 (-)	Dec ctr	Dec ctr
0 (-)	x	x	No action	No action
1 (inc)	0 (-)	1 (inv)	Inc ctr	Dec ctr
1 (inc)	1 (inv)	0 (-)	Dec ctr	Inc ctr
2 (dec)	0 (-)	1 (inv)	Dec ctr	Inc ctr
1 (inc)	0 (-)	2 (dis)	Inc ctr	No action
1 (inc)	2 (dis)	0 (-)	No action	Inc ctr

This table is also valid for negative edges (sig h→l) on substituting NEG_MODE for POS_MODE.

Each pulse counter unit also features a filter on each of the four inputs, adding the option to ignore short glitches in the signals. If a PCNT_FILTER_EN_Un can be set to filter the four input signals of the unit. If this filter is enabled, any pulses shorter than REG_FILTER_THRES_Un number of APB_CLK clock cycles will be filtered out and will have no effect on the counter. With the filter disabled, in theory infinitely small glitches could possibly trigger pulse counter action. However, in practice the signal inputs are sampled on APB_CLK edges and even with the filter disabled, pulse widths lasting shorter than one APB_CLK cycle may be missed.

Apart from the input channels, software also has some control over the counter. In particular, the counter value can be frozen to the current value by configuring PCNT_CNT_PAUSE_Un. It can also be reset to 0 by configuring PCNT_PULSE_CNT_RST_Un.

11.2.3 Watchpoints

The pulse counters have five watchpoints that share one interrupt. Interrupt generation can be enabled or disabled for each individual watchpoint. The watchpoints are:

- Maximum count value: Triggered when PULSE_CNT >= PCNT_THR_H_LIM_Un. Additionally, this will reset the counter to 0.
- Minimum count value: Triggered when PULSE_CNT <= PCNT_THR_L_LIM_Un. Additionally, this will reset the counter to 0. This is most useful when PCNT_THR_L_LIM_Un is set to a negative number.
- Two threshold values: Triggered when PULSE_CNT = PCNT_THR_THRES0_Or or PCNT_THR_THRES1_Or.
- Zero: Triggered when PULSE_CNT = 0.

11.2.4 Examples

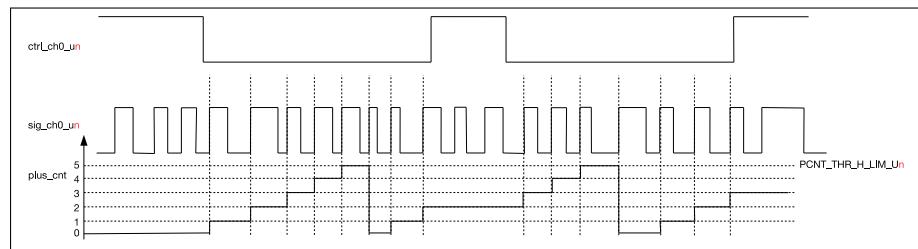

Figure 58: PULSE_CNT Upcounting Diagram

Figure 58 shows channel 0 being used as an up-counter. The configuration of channel 0 is shown below.

- CNT_CH0_POS_MODE_Un = 1: increase counter on the rising edge of sig_ch0_un.
- PCNT_CH0_NEG_MODE_Un = 0: no counting on the falling edge of sig_ch0_un.
- PCNT_CH0_LCTRL_MODE_Un = 0: Do not modify counter mode when sig_ch0_un is low.
- PCNT_CH0_HCTRL_MODE_Un = 2: Do not allow counter increments/decrements when sig_ch0_un is high.
- PCNT_THR_H_LIM_Un = 5: PULSE_CNT resets to 0 when the count value increases to 5.

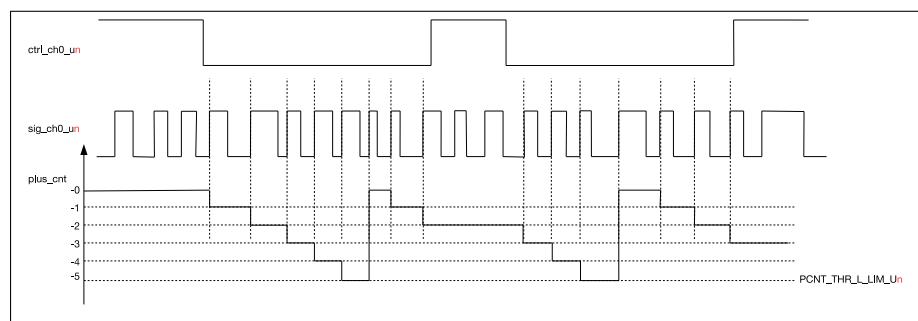

Figure 59: PULSE_CNT Downcounting Diagram

Figure 59 shows channel 0 decrementing the counter. The configuration of channel 0 differs from that in Figure 58 in the following two aspects:

- PCNT_CH0_LCTRL_MODE_Un = 1: invert counter mode when ctrl_ch0_un is at low level, so it will decrease, rather than increase, the counter.
- PCNT_THR_H_LIM_Un = -5: PULSE_CNT resets to 0 when the count value decreases to -5.

11.2.5 Interrupts

PCNT_CNT_THR_EVENT_Un_INT: This interrupt gets triggered when one of the five channel comparators detects a match.

12. 64-bit Timers

12.1 Introduction

There are four general-purpose timers embedded in the ESP32. They are all 64-bit generic timers based on 16-bit prescalers and 64-bit auto-reload-capable up/downcounters.

The ESP32 contains two timer modules, each containing two timers. The two timers in a block are indicated by an *x* in `TIMGn_Tx`; the blocks themselves are indicated by an *n*.

The timers feature:

- A 16-bit clock prescaler, from 2 to 65536
- A 64-bit time-base counter
- Configurable up/down time-base counter: incrementing or decrementing
- Halt and resume of time-base counter
- Auto-reload at alarm
- Software-controlled instant reload
- Level and edge interrupt generation

12.2 Functional Description

12.2.1 16-bit Prescaler

Each timer uses the APB clock (APB_CLK, normally 80 MHz) as the basic clock. This clock is then divided down by a 16-bit prescaler which generates the time-base counter clock (TB_clk). Every cycle of TB_clk causes the time-base counter to increment or decrement by one. The timer must be disabled (`TIMGn_Tx_EN` is cleared) before changing the prescaler divisor which is configured by `TIMGn_Tx_DIVIDER` register; changing it on an enabled timer can lead to unpredictable results. The prescaler can divide the APB clock by a factor from 2 to 65536. Specifically, when `TIMGn_Tx_DIVIDER` is either 1 or 2, the clock divisor is 2; when `TIMGn_Tx_DIVIDER` is 0, the clock divisor is 65536. Any other value will cause the clock to be divided by exactly that value.

12.2.2 64-bit Time-base Counter

The 64-bit time-base counter can be configured to count either up or down, depending on whether `TIMGn_Tx_INCREASE` is set or cleared, respectively. It supports both auto-reload and software instant reload. An alarm event can be set when the counter reaches a value specified by the software.

Counting can be enabled and disabled by setting and clearing `TIMGn_Tx_EN`. Clearing this bit essentially freezes the counter, causing it to neither count up nor count down; instead, it retains its value until `TIMGn_Tx_EN` is set again. Reloading the counter when `TIMGn_Tx_EN` is cleared will change its value, but counting will not be resumed until `TIMGn_Tx_EN` is set.

Software can set a new counter value by setting registers `TIMGn_Tx_LOAD_LO` and `TIMGn_Tx_LOAD_HI` to the intended new value. The hardware will ignore these register settings until a reload; a reload will cause the contents of these registers to be copied to the counter itself. A reload event can be triggered by an alarm (auto-reload at alarm) or by software (software instant reload). To enable auto-reload at alarm, the register

`TIMGn_Tx_AUTORELOAD` should be set. If auto-reload at alarm is not enabled, the time-base counter will continue incrementing or decrementing after the alarm. To trigger a software instant reload, any value can be written to the register `TIMGn_Tx_LOAD_REG`; this will cause the counter value to change instantly. Software can also change the direction of the time-base counter instantly by changing the value of `TIMGn_Tx_INCREASE`.

The time-base counter can also be read by software, but because the counter is 64-bit, the CPU can only get the value as two 32-bit values, the counter value needs to be latched onto `TIMGn_TxLO_REG` and `TIMGn_TxHI_REG` first. This is done by writing any value to `TIMGn_TxUPDATE_REG`; this will instantly latch the 64-bit timer value onto the two registers. Software can then read them at any point in time. This approach stops the timer value being read erroneously when a carry-over happens between reading the low and high word of the timer value.

12.2.3 Alarm Generation

The timer can trigger an alarm, which can cause a reload and/or an interrupt to occur. The alarm is triggered when the alarm registers `TIMGn_Tx_ALARMLO_REG` and `TIMGn_Tx_ALARMHI_REG` match the current timer value. In order to simplify the scenario where these registers are set 'too late' and the counter has already passed these values, the alarm also triggers when the current timer value is higher (for an up-counting timer) or lower (for a down-counting timer) than the current alarm value: if this is the case, the alarm will be triggered immediately upon loading the alarm registers.

12.2.4 MWDT

Each timer module also contains a Main System Watchdog Timer and its associated registers. While these registers are described here, their functional description can be found in the chapter entitled [Watchdog Timer](#).

12.2.5 Interrupts

- `TIMGn_Tx_INT_WDT_INT`: Generated when a watchdog timer interrupt stage times out.
- `TIMGn_Tx_INT_T1_INT`: An alarm event on timer 1 generates this interrupt.
- `TIMGn_Tx_INT_T0_INT`: An alarm event on timer 0 generates this interrupt.

13. Watchdog Timers

13.1 Introduction

The ESP32 has three watchdog timers: one in each of the two timer modules (called Main System Watchdog Timer, or MWDT) and one in the RTC module (which is called the RTC Watchdog Timer, or RWDT). These watchdog timers are intended to recover from an unforeseen fault, causing the application program to abandon its normal sequence. A watchdog timer has four stages. Each stage may take one out of three or four actions upon the expiry of a programmed period of time for this stage, unless the watchdog is fed or disabled. The actions are: interrupt, CPU reset, core reset and system reset. Only the RWDT can trigger the system reset, and is able to reset the entire chip and the main system including the RTC itself. A timeout value can be set for each stage individually.

During flash boot, the RWDT and the first MWDT start automatically in order to detect and recover from booting problems.

13.2 Features

- Four stages, each of which can be configured or disabled separately
- Programmable time period for each stage
- One out of three or four possible actions (interrupt, CPU reset, core reset and system reset) upon the expiry of each stage
- 32-bit expiry counter
- Write protection, to prevent the RWDT and MWDT configuration from being inadvertently altered.
- Flash boot protection

If the boot process from an SPI flash does not complete within a predetermined period of time, the watchdog will reboot the entire main system.

13.3 Functional Description

13.3.1 Clock

The RWDT is clocked from the RTC slow clock, which usually will be 32 KHz. The MWDT clock source is derived from the APB clock via a pre-MWDT 16-bit configurable prescaler. For either watchdog, the clock source is fed into the 32-bit expiry counter. When this counter reaches the timeout value of the current stage, the action configured for the stage will execute, the expiry counter will be reset and the next stage will become active.

13.3.1.1 Operating Procedure

When a watchdog timer is enabled, it will proceed in loops from stage 0 to stage 3, then back to stage 0 and start again. The expiry action and time period for each stage can be configured individually.

Every stage can be configured for one of the following actions when the expiry timer reaches the stage's timeout value:

- Trigger an interrupt

When the stage expires an interrupt is triggered.

- Reset a CPU core

When the stage expires the designated CPU core will be reset. MWDT0 CPU reset only resets the PRO CPU. MWDT1 CPU reset only resets the APP CPU. The RWDT CPU reset can reset either of them, or both, or none, depending on configuration.

- Reset the main system

When the stage expires, the main system, including the MWDTs, will be reset. In this article, the main system includes the CPU and all peripherals. The RTC is an exception to this, and it will not be reset.

- Reset the main system and RTC

When the stage expires the main system and the RTC will both be reset. This action is only available in the RWDT.

- Disabled

This stage will have no effects on the system.

When software feeds the watchdog timer, it returns to stage 0 and its expiry counter restarts from 0.

13.3.1.2 Write Protection

Both the MWDTs, as well as the RWDT, can be protected from accidental writing. To accomplish this, they have a write-key register (TIMERS_WDT_WKEY for the MWDT, RTC_CNTL_WDT_WKEY for the RWDT.) On reset, these registers are initialized to the value 0x50D83AA1. When the value in this register is changed from 0x50D83AA1, write protection is enabled. Writes to any WDT register, including the feeding register (but excluding the write-key register itself), are ignored. The recommended procedure for accessing a WDT is:

1. Disable the write protection
2. Make the required modification or feed the watchdog
3. Re-enable the write protection

13.3.1.3 Flash Boot Protection

During flash booting, the MWDT in timer group 0 ([TIMG0](#)), as well as the RWDT, are automatically enabled. Stage 0 for the enabled MWDT is automatically configured to reset the system upon expiry; stage 0 for the RWDT resets the RTC when it expires. After booting, the register TIMERS_WDT_FLASHBOOT_MOD_EN should be cleared to stop the flash boot protection procedure for the MWDT, and RTC_CNTL_WDT_FLASHBOOT_MOD_EN should be cleared to do the same for the RWDT. After this, the MWDT and RWDT can be configured by software.

13.3.1.4 Registers

The MWDT registers are part of the timer submodule and are described in the [Timer Registers](#) section. The RWDT registers are part of the RTC submodule and are described in the [RTC Registers](#) section.

14. eFuse Controller

14.1 Introduction

The ESP32 has a number of eFuses which store system parameters. Fundamentally, an eFuse is a single bit of non-volatile memory with the restriction that once an eFuse bit is programmed to 1, it can never be reverted to 0. Software can instruct the eFuse Controller to program each bit for each system parameter as needed.

Some of these system parameters can be read by software using the eFuse Controller. Some of the system parameters are also directly used by hardware modules.

14.2 Features

- Configuration of 26 system parameters
- Optional write-protection
- Optional software-read-protection

14.3 Functional Description

14.3.1 Structure

Twenty-six system parameters with different bit width are stored in the eFuses. The name of each system parameter and the corresponding bit width are shown in Table 42. Among those parameters, efuse_wr_disable, efuse_rd_disable, and coding_scheme are directly used by the eFuse Controller.

Table 42: System Parameter

Name	Bit width	Program -Protection by efuse_wr_disable	Software-Read -Protection by efuse_rd_disable	Description
efuse_wr_disable	16	1	-	controls the eFuse Controller
efuse_rd_disable	4	0	-	controls the eFuse Controller
flash_crypt_cnt	8	2	-	governs the flash encryption/decryption
WIFI_MAC_Address	56	3	-	Wi-Fi MAC address and CRC

BLOCK2	256/192/128	8	1	key for Secure Boot
BLOCK3	256/192/128	9	2	key for user purposes

14.3.1.1 System Parameter efuse_wr_disable

The system parameter efuse_wr_disable determines whether all of the system parameters are write-protected. Since efuse_wr_disable is a system parameter as well, it also determines whether it itself is write-protected.

If a system parameter is not write-protected, its unprogrammed bits can be programmed from 0 to 1. The bits previously programmed to 1 will remain 1. When a system parameter is write-protected, none of its bits can be programmed: The unprogrammed bits will always remain 0 and the programmed bits will always remain 1.

The write-protection status of each system parameter corresponds to a bit in efuse_wr_disable. When the corresponding bit is set to 0, the system parameter is not write-protected. When the corresponding bit is set to 1, the system parameter is write-protected. If a system parameter is already write-protected, it will remain write-protected. The column entitled "Program-Protection by efuse_wr_disable" in Table 42 lists the corresponding bits that determine the write-protection status of each system parameter.

14.3.1.2 System Parameter efuse_rd_disable

Of the 26 system parameters, 20 are not constrained by software-read-protection. These are marked by "-" in the column entitled "Software-Read-Protection by efuse_rd_disable" in Table 42. Those system parameters, some of which are used by software and hardware modules at the same time, can be read by software via the eFuse Controller at any time.

When not software-read-protected, the other six system parameters can both be read by software and used by hardware modules. When they are software-read-protected, they can only be used by the hardware modules.

The column "Software-Read-Protection by efuse_rd_disable" in Table 42 lists the corresponding bits in efuse_rd_disable that determine the software read-protection status of the six system parameters. If a bit in the system parameter efuse_rd_disable is 0, the system parameter controlled by the bit is not software-read-protected. If a bit in the system parameter efuse_rd_disable is 1, the system parameter controlled by the bit is software-read-protected. If a system parameter is software-read-protected, it will remain in this state.

14.3.1.3 System Parameter coding_scheme

As Table 42 shows, only three system parameters, BLOCK1, BLOCK2, and BLOCK3, have variable bit width. Their bit width is controlled by another system parameter, coding_scheme. Despite their variable bit width, BLOCK1, BLOCK2, and BLOCK3 are assigned a fixed number of bits in eFuse. There is an encoding mapping between these three system parameters and their corresponding stored values in eFuse. For details please see Table 43.

Table 43: BLOCK1/2/3 Encoding

coding_scheme[1:0]	Width of BLOCK1/2/3	Coding scheme	Number of bits in eFuse
00/11	256	None	256
01	192	3/4	256
10	128	Repeat	256

The three coding schemes are explained as follows:

- *BLOCKN* represents any of the following three system parameters: BLOCK1, BLOCK2 or BLOCK3.
- *BLOCKN[255 : 0]*, *BLOCKN[191 : 0]*, and *BLOCKN[127 : 0]* represent each bit of the three system parameters in the three encoding schemes.
- ^e*BLOCKN[255 : 0]* represents each corresponding bit of those system parameters in eFuse after being encoded.

14.3.2 Programming of System Parameters

The programming of variable-length system parameters BLOCK1, BLOCK2, and BLOCK3 is different from that of the fixed-length system parameters. **We program the ${}^e BLOCKN[255 : 0]$ value of encoded system parameters BLOCK1, BLOCK2, and BLOCK3 instead of directly programming the system parameters.**

The bit width of ${}^e BLOCKN[255 : 0]$ is always 256. Fixed-length system parameters, in contrast, are programmed without encoding them first.

Each bit of the 23 fixed-length system parameters and the three encoded variable-length system parameters corresponds to a program register bit, as shown in Table 44. The register bits will be used when programming system parameters.

The process of programming system parameters is as follows:

1. Configure EFUSE_CLK_SEL0 bit, EFUSE_CLK_SEL1 bit of register EFUSE_CLK, and EFUSE_DAC_CLK_DIV bit of register EFUSE_DAC_CONF.
2. Set the corresponding register bit of the system parameter bit to be programmed to 1.

3. Write 0x5A5A into register EFUSE_CONF.
4. Write 0x2 into register EFUSE_CMD.
5. Poll register EFUSE_CMD until it is 0x0, or wait for a program-done interrupt.
6. Write 0x5AA5 into register EFUSE_CONF.
7. Write 0x1 into register EFUSE_CMD.
8. Poll register EFUSE_CMD until it is 0x0, or wait for a read-done interrupt.
9. Set the corresponding register bit of the programmed bit to 0.

The configuration values of the EFUSE_CLK_SEL0 bit, EFUSE_CLK_SEL1 bit of register EFUSE_CLK, and the EFUSE_DAC_CLK_DIV bit of register EFUSE_DAC_CONF are based on the current APB_CLK frequency, as is shown in Table 45.

Table 45: Timing Configuration

Configuration Value		APB_CLK Frequency	26 MHz	40 MHz	80 MHz
Register					
EFUSE_CLK	EFUSE_CLK_SEL0[7:0]	8'd250	8'd160	8'd80	
	EFUSE_CLK_SEL1[7:0]	8'd255	8'd255	8'd128	
EFUSE_DAC_CONF	EFUSE_DAC_CLK_DIV[7:0]	8'd52	8'd80	8'd160	

The two methods to identify the generation of program/read-done interrupts are as follows:

Method One:

1. Poll bit 1/0 in register EFUSE_INT_RAW until bit 1/0 is 1, which represents the generation of an program/read-done interrupt.
2. Set the bit 1/0 in register EFUSE_INT_CLR to 1 to clear the program/read-done interrupts.

Method Two:

1. Set bit 1/0 in register EFUSE_INT_ENA to 1 to enable eFuse Controller to post a program/read-done interrupt.
2. Configure Interrupt Matrix to enable the CPU to respond to an EFUSE_INT interrupt.
3. A program/read-done interrupt is generated.
4. Read bit 1/0 in register EFUSE_INT_ST to identify the generation of the program/read-done interrupt.
5. Set bit 1/0 in register EFUSE_INT_CLR to 1 to clear the program/read-done interrupt.

The programming of different system parameters and even the programming of different bits of the same system parameter can be completed separately in multiple programmings. It is, however, recommended that users minimize programming cycles, and program all the bits that need to be programmed in a system parameter in one programming action. In addition, after all system parameters controlled by a certain bit of efuse_wr_disable are programmed, that bit should be immediately programmed. The programming of system parameters controlled by a certain bit of efuse_wr_disable, and the programming of that bit can even be completed at the same time. **Repeated programming of programmed bits is strictly forbidden.**

14.3.3 Software Reading of System Parameters

Each bit of the 23 fixed-length system parameters and the three variable-length system parameters corresponds to a software-read register bit, as shown in Table 46. Software can use the value of each system parameter by reading the value in the corresponding register.

The bit width of system parameters BLOCK1, BLOCK2, and BLOCK3 is variable. Although 256 register bits have been assigned to each of the three parameters, as shown in Table 46, some of the 256 register bits are useless in the 3/4 coding and the Repeat coding scheme. In the None coding scheme, the corresponding register bit of each bit of $BLOCKN[255 : 0]$ is used. In the 3/4 coding scheme, only the corresponding register bits of $BLOCKN[191 : 0]$ are useful. In Repeat coding scheme, only the corresponding bits of $BLOCKN[127 : 0]$ are useful. In different coding schemes, the values of useless register bits read by software are invalid. **The values of useful register bits read by software are the system parameters BLOCK1, BLOCK2, and BLOCK3 themselves instead of their values after being encoded.**

14.3.4 The Use of System Parameters by Hardware Modules

Hardware modules are directly hardwired to the ESP32 in order to use the system parameters. Software cannot change this behaviour. **Hardware modules use the decoded values of system parameters BLOCK1, BLOCK2, and BLOCK3, not their encoded values.**

14.3.5 Interrupts

- EFUSE_PGM_DONE_INT: Triggered when eFuse programming has finished.
- EFUSE_READ_DONE_INT: Triggered when eFuse reading has finished.

15. AES Accelerator

15.1 Introduction

The AES Accelerator speeds up AES operations significantly, compared to AES algorithms implemented solely in software. The AES Accelerator supports six algorithms of FIPS PUB 197, specifically AES-128, AES-192 and AES-256 encryption and decryption.

15.2 Features

- Supports AES-128 encryption and decryption
- Supports AES-192 encryption and decryption
- Supports AES-256 encryption and decryption
- Supports four variations of key endianness and four variations of text endianness

15.3 Functional Description

15.3.1 AES Algorithm Operations

The AES Accelerator supports six algorithms of FIPS PUB 197, specifically AES-128, AES-192 and AES-256 encryption and decryption. The AES_MODE_REG register can be configured to different values to enable different algorithm operations, as shown in Table 48.

Table 48: Operation Mode

AES_MODE_REG[2:0]	Operation
0	AES-128 Encryption
1	AES-192 Encryption
2	AES-256 Encryption
4	AES-128 Decryption
5	AES-192 Decryption
6	AES-256 Decryption

15.3.2 Key, Plaintext and Ciphertext

The encryption or decryption key is stored in AES_KEY_ *n* _REG, which is a set of eight 32-bit registers. For AES-128 encryption/decryption, the 128-bit key is stored in AES_KEY_0_REG ~ AES_KEY_3_REG. For AES-192 encryption/decryption, the 192-bit key is stored in AES_KEY_0_REG ~ AES_KEY_5_REG. For AES-256 encryption/decryption, the 256-bit key is stored in AES_KEY_0_REG ~ AES_KEY_7_REG.

Plaintext and ciphertext is stored in the AES_TEXT_ *m* _REG registers. There are four 32-bit registers. To enable AES-128/192/256 encryption, initialize the AES_TEXT_ *m* _REG registers with plaintext before encryption. When encryption is finished, the AES Accelerator will store back the resulting ciphertext in the AES_TEXT_ *m* _REG registers. To enable AES-128/192/256 decryption, initialize the AES_TEXT_ *m* _REG registers with ciphertext before decryption. When decryption is finished, the AES Accelerator will store back the resulting plaintext in the AES_TEXT_ *m* _REG registers.

15.3.3 Endianness

Key Endianness

Bit 0 and bit 1 in AES_ENDIAN_REG define the key endianness. For detailed information, please see Table 50, Table 51 and Table 52. w[0] ~ w[3] in Table 50, w[0] ~ w[5] in Table 51 and w[0] ~ w[7] in Table 52 are “the first Nk words of the expanded key” as specified in “5.2: Key Expansion” of FIPS PUB 197. “Column Bit” specifies the bytes in the word from w[0] to w[7]. The bytes of AES_KEY_n_REG comprise “the first Nk words of the expanded key”.

Text Endianness

Bit 2 and bit 3 in AES_ENDIAN_REG define the endianness of input text, while Bit 4 and Bit 5 define the endianness of output text. The input text refers to the plaintext in AES-128/192/256 encryption and the ciphertext in decryption. The output text refers to the ciphertext in AES-128/192/256 encryption and the plaintext in decryption. For details, please see Table 49. “State” in Table 49 is defined as that in “3.4: The State” of FIPS PUB 197: “The AES algorithm operations are performed on a two-dimensional array of bytes called the State”. The ciphertext or plaintexts stored in each byte of AES_TEXT_m_REG comprise the State.

15.3.4 Encryption and Decryption Operations

Single Operation

1. Initialize AES_MODE_REG, AES_KEY_*n*_REG, AES_TEXT_*m*_REG and AES_ENDIAN_REG.
2. Write 1 to AES_START_REG.
3. Wait until AES_IDLE_REG reads 1.
4. Read results from AES_TEXT_*m*_REG.

Consecutive Operations

Every time an operation is completed, only AES_TEXT_*m*_REG is modified by the AES Accelerator. Initialization can, therefore, be simplified in a series of consecutive operations.

1. Update contents of AES_MODE_REG, AES_KEY_*n*_REG and AES_ENDIAN_REG, if required.
2. Load AES_TEXT_*m*_REG.
3. Write 1 to AES_START_REG.
4. Wait until AES_IDLE_REG reads 1.
5. Read results from AES_TEXT_*m*_REG.

15.3.5 Speed

The AES Accelerator requires 11 to 15 clock cycles to encrypt a message block, and 21 or 22 clock cycles to decrypt a message block.

16. SHA Accelerator

16.1 Introduction

The SHA Accelerator is included to speed up SHA hashing operations significantly, compared to SHA hashing algorithms implemented solely in software. The SHA Accelerator supports four algorithms of FIPS PUB 180-4, specifically SHA-1, SHA-256, SHA-384 and SHA-512.

16.2 Features

Hardware support for popular secure hashing algorithms:

- SHA-1
- SHA-256
- SHA-384
- SHA-512

16.3 Functional Description

16.3.1 Padding and Parsing the Message

The SHA Accelerator can only accept one message block at a time. Software divides the message into blocks according to “5.2 Parsing the Message” in FIPS PUB 180-4 and writes one block to the `SHA_TEXT_n_REG` registers each time. For SHA-1 and SHA-256, software writes a 512-bit message block to `SHA_TEXT_0_REG ~ SHA_TEXT_15_REG` each time. For SHA-384 and SHA-512, software writes a 1024-bit message block to `SHA_TEXT_0_REG ~ SHA_TEXT_31_REG` each time.

The SHA Accelerator is unable to perform the padding operation of “5.1 Padding the Message” in FIPS PUB 180-4; Note that the user software is expected to pad the message before feeding it into the accelerator.

As described in “2.2.1: Parameters” in FIPS PUB 180-4, “ $M_0^{(i)}$ is the leftmost word of message block i”. $M_0^{(i)}$ is stored in `SHA_TEXT_0_REG`. In the same fashion, the `SHA_TEXT_1_REG` register stores the second left-most word of a message block $H_1^{(N)}$, etc.

16.3.2 Message Digest

When the hashing operation is finished, the message digest will be refreshed by SHA Accelerator and will be stored in `SHA_TEXT_n_REG`. SHA-1 produces a 160-bit message digest and stores it in `SHA_TEXT_0_REG ~ SHA_TEXT_4_REG`. SHA-256 produces a 256-bit message digest and stores it in `SHA_TEXT_0_REG ~ SHA_TEXT_7_REG`. SHA-384 produces a 384-bit message digest and stores it in `SHA_TEXT_0_REG ~ SHA_TEXT_11_REG`. SHA-512 produces a 512-bit message digest and stores it in `SHA_TEXT_0_REG ~ SHA_TEXT_15_REG`.

As described in “2.2.1 Parameters” in FIPS PUB 180-4, “ $H^{(N)}$ is the final hash value, and is used to determine the message digest”, while “ $H_0^{(i)}$ is the leftmost word of hash value i”, so the leftmost word $H_0^{(N)}$ in the message digest is stored in `SHA_TEXT_0_REG`. In the same fashion, the second leftmost word $H_1^{(N)}$ in the message digest is stored in `SHA_TEXT_1_REG`, etc.

16.3.3 Hash Operation

There is a set of control registers for SHA-1, SHA-256, SHA-384 and SHA-512, respectively; different hashing algorithms use different control registers.

SHA-1 uses SHA_SHA1_START_REG, SHA_SHA1_CONTINUE_REG, SHA_SHA1_LOAD_REG and SHA_SHA1_BUSY_REG.

SHA-256 uses SHA_SHA256_START_REG, SHA_SHA256_CONTINUE_REG, SHA_SHA256_LOAD_REG and SHA_SHA256_BUSY_REG. SHA-384 uses SHA_SHA384_START_REG, SHA_SHA384_CONTINUE_REG, SHA_SHA384_LOAD_REG and SHA_SHA384_BUSY_REG.

SHA-512 uses SHA_SHA512_START_REG, SHA_SHA512_CONTINUE_REG, SHA_SHA512_LOAD_REG and SHA_SHA512_BUSY_REG. The following steps describe the operation in a detailed manner.

1. Feed the accelerator with the first message block:
 - (a) Use the first message block to initialize SHA_TEXT_0_REG.
 - (b) Write 1 to SHA_X_START_REG.
 - (c) Wait for SHA_X_BUSY_REG to read 0, indicating that the operation is completed.
2. Similarly, feed the accelerator with subsequent message blocks:
 - (a) Initialize SHA_TEXT_n_REG using the subsequent message block.
 - (b) Write 1 to SHA_X_CONTINUE_REG.
 - (c) Wait for SHA_X_BUSY_REG to read 0, indicating that the operation is completed.
3. Get message digest:
 - (a) Write 1 to SHA_X_LOAD_REG.
 - (b) Wait for SHA_X_BUSY_REG to read 0, indicating that operation is completed.
 - (c) Read message digest from SHA_TEXT_n_REG.

16.3.4 Speed

The SHA Accelerator requires 60 to 100 clock cycles to process a message block and 8 to 20 clock cycles to calculate the final digest.

17. RSA Accelerator

17.1 Introduction

The RSA Accelerator provides hardware support for multiple precision arithmetic operations used in RSA asymmetric cipher algorithms.

Sometimes, multiple precision arithmetic is also called "bignum arithmetic", "bigint arithmetic" or "arbitrary precision arithmetic".

17.2 Features

- Support for large-number modular exponentiation
- Support for large-number modular multiplication
- Support for large-number multiplication
- Support for various lengths of operands

17.3 Functional Description

17.3.1 Initialization

The RSA Accelerator is activated by enabling the corresponding peripheral clock, and by clearing the DPORT_RSA_PD bit in the DPORT_RSA_PD_CTRL_REG register. This releases the RSA Accelerator from reset.

When the RSA Accelerator is released from reset, the register RSA_CLEAN_REG reads 0 and an initialization process begins. Hardware initializes the four memory blocks by setting them to 0. After initialization is complete, RSA_CLEAN_REG reads 1. For this reason, software should query RSA_CLEAN_REG after being released from reset, and before writing to any RSA Accelerator memory blocks or registers for the first time.

17.3.2 Large Number Modular Exponentiation

Large-number modular exponentiation performs $Z = X^Y \bmod M$. The operation is based on Montgomery multiplication. Aside from the arguments X , Y , and M , two additional ones are needed — \bar{r} and M' . These arguments are calculated in advance by software.

The RSA Accelerator supports operand lengths of $N \in \{512, 1024, 1536, 2048, 2560, 3072, 3584, 4096\}$ bits. The bit length of arguments Z , X , Y , M , and \bar{r} can be any one from the N set, but all numbers in a calculation must be of the same length. The bit length of M' is always 32.

To represent the numbers used as operands, define a base- b positional notation, as follows:

$$b = 2^{32}$$

In this notation, each number is represented by a sequence of base- b digits, where each base- b digit is a 32-bit word. Representing an N -bit number requires n base- b digits (all of the possible N lengths are multiples of 32).

$$n = \frac{N}{32}$$

$$Z = (Z_{n-1} Z_{n-2} \cdots Z_0)_b$$

$$X = (X_{n-1} X_{n-2} \cdots X_0)_b$$

$$Y = (Y_{n-1} Y_{n-2} \cdots Y_0)_b$$

$$M = (M_{n-1} M_{n-2} \cdots M_0)_b$$

$$\bar{r} = (\bar{r}_{n-1} \bar{r}_{n-2} \cdots \bar{r}_0)_b$$

Each of the n values in $Z_{n-1} \sim Z_0$, $X_{n-1} \sim X_0$, $Y_{n-1} \sim Y_0$, $M_{n-1} \sim M_0$, $\bar{r}_{n-1} \sim \bar{r}_0$ represents one base- b digit (a 32-bit word).

Z_{n-1} , X_{n-1} , Y_{n-1} , M_{n-1} and \bar{r}_{n-1} are the most significant bits of Z , X , Y , M , while Z_0 , X_0 , Y_0 , M_0 and \bar{r}_0 are the least significant bits.

If we define

$$R = b^n$$

then, we can calculate the additional arguments, as follows:

$$\bar{r} = R^2 \bmod M \tag{1}$$

$$\begin{cases} M'' \times M + 1 = R \times R^{-1} \\ M' = M'' \bmod b \end{cases} \tag{2}$$

(Equation 2 is written in a form suitable for calculations using the extended binary GCD algorithm.)

Software can implement large-number modular exponentiations in the following order:

1. Write $(\frac{N}{512} - 1)$ to RSA_MODEXP_MODE_REG.
2. Write X_i , Y_i , M_i and \bar{r}_i ($i \in [0, n] \cap \mathbb{N}$) to memory blocks RSA_X_MEM, RSA_Y_MEM, RSA_M_MEM and RSA_Z_MEM. The capacity of each memory block is 128 words. Each word of each memory block can store one base- b digit. The memory blocks use the little endian format for storage, i.e. the least significant digit of each number is in the lowest address.
Users need to write data to each memory block only according to the length of the number; data beyond this length are ignored.
3. Write M' to RSA_M_PRIME_REG.
4. Write 1 to RSA_MODEXP_START_REG.
5. Wait for the operation to be completed. Poll RSA_INTERRUPT_REG until it reads 1, or until the RSA_INTR interrupt is generated.
6. Read the result Z_i ($i \in [0, n] \cap \mathbb{N}$) from RSA_Z_MEM.
7. Write 1 to RSA_INTERRUPT_REG to clear the interrupt.

After the operation, the RSA_MODEXP_MODE_REG register, memory blocks RSA_Y_MEM and RSA_M_MEM, as well as the RSA_M_PRIME_REG will not have changed. However, X_i in RSA_X_MEM and \bar{r}_i in RSA_Z_MEM

will have been overwritten. In order to perform another operation, refresh the registers and memory blocks, as required.

17.3.3 Large Number Modular Multiplication

Large-number modular multiplication performs $Z = X \times Y \bmod M$. This operation is based on Montgomery multiplication. The same values \bar{r} and M' are derived by software using the formulas 1 and 2 shown above.

The RSA Accelerator supports large-number modular multiplication with eight different operand lengths, which are the same as in the large-number modular exponentiation. The operation is performed by a combination of software and hardware. The software performs two hardware operations in sequence.

The software process is as follows:

1. Write $(\frac{N}{512} - 1)$ to RSA_MULT_MODE_REG.
2. Write X_i , M_i and \bar{r}_i ($i \in [0, n] \cap \mathbb{N}$) to registers RSA_X_MEM, RSA_M_MEM and RSA_Z_MEM. Write data to each memory block only according to the length of the number. Data beyond this length are ignored.
3. Write M' to RSA_M_PRIME_REG.
4. Write 1 to RSA_MULT_START_REG.
5. Wait for the first round of the operation to be completed. Poll RSA_INTERRUPT_REG until it reads 1, or until the RSA_INTR interrupt is generated.
6. Write 1 to RSA_INTERRUPT_REG to clear the interrupt.
7. Write Y_i ($i \in [0, n] \cap \mathbb{N}$) to RSA_X_MEM.

Users need to write to the memory block only according to the length of the number. Data beyond this length are ignored.

8. Write 1 to RSA_MULT_START_REG.
9. Wait for the second round of the operation to be completed. Poll RSA_INTERRUPT_REG until it reads 1, or until the RSA_INTR interrupt is generated.
10. Read the result Z_i ($i \in [0, n] \cap \mathbb{N}$) from RSA_Z_MEM.
11. Write 1 to RSA_INTERRUPT_REG to clear the interrupt.

After the operation, the RSA_MULT_MODE_REG register, and memory blocks RSA_M_MEM and RSA_M_PRIME_REG remain unchanged. Users do not need to refresh these registers or memory blocks if the values remain the same.

17.3.4 Large Number Multiplication

Large-number multiplication performs $Z = X \times Y$. The length of Z is twice that of X and Y . Therefore, the RSA Accelerator supports large-number multiplication with only four operand lengths of $N \in \{512, 1024, 1536, 2048\}$ bits. The length \hat{N} of the result Z is $2 \times N$ bits.

Operands X and Y need to be extended to form arguments \hat{X} and \hat{Y} which have the same length (\hat{N} bits) as

the result Z . X is left-extended and Y is right-extended, and defined as follows:

$$\begin{aligned} n &= \frac{N}{32} \\ \hat{N} &= 2 \times N \\ \hat{n} &= \frac{\hat{N}}{32} = 2n \\ \hat{X} &= (\hat{X}_{\hat{n}-1}\hat{X}_{\hat{n}-2}\cdots\hat{X}_0)_b = (\underbrace{00\cdots 0}_n X)_b = (\underbrace{00\cdots 0}_n X_{n-1}X_{n-2}\cdots X_0)_b \\ \hat{Y} &= (\hat{Y}_{\hat{n}-1}\hat{Y}_{\hat{n}-2}\cdots\hat{Y}_0)_b = (Y \underbrace{00\cdots 0}_n)_b = (Y_{n-1}Y_{n-2}\cdots Y_0 \underbrace{00\cdots 0}_n)_b \end{aligned}$$

Software performs the operation in the following order:

1. Write $(\frac{\hat{N}}{512} - 1 + 8)$ to RSA_MULT_MODE_REG.
2. Write \hat{X}_i and \hat{Y}_i ($i \in [0, \hat{n}] \cap \mathbb{N}$) to RSA_X_MEM and RSA_Z_MEM, respectively.

Write the valid data into each number's memory block, according to their lengths. Values beyond this length are ignored. Half of the base- b positional notations written to the memory are zero (using the derivations shown above). These zero values are indispensable.

3. Write 1 to RSA_MULT_START_REG.
4. Wait for the operation to be completed. Poll RSA_INTERRUPT_REG until it reads 1, or until the RSA_INTR interrupt is generated.
5. Read the result Z_i ($i \in [0, \hat{n}] \cap \mathbb{N}$) from RSA_Z_MEM.
6. Write 1 to RSA_INTERRUPT_REG to clear the interrupt.

After the operation, only the RSA_MULT_MODE_REG register remains unmodified.

18. Random Number Generator

18.1 Introduction

The ESP32 contains a true random number generator, whose values can be used as a basis for cryptographical operations, among other things.

18.2 Feature

It can generate true random numbers.

18.3 Functional Description

When used correctly, every 32-bit value the system reads from the RNG_DATA_REG register of the random number generator is a true random number. These true random numbers are generated based on the noise in the Wi-Fi/BT RF system. When Wi-Fi and BT are disabled, the random number generator will give out pseudo-random numbers.

When Wi-Fi or BT is enabled, the random number generator is fed two bits of entropy every APB clock cycle (normally 80 MHz). Thus, for the maximum amount of entropy, it is advisable to read the random register at a maximum rate of 5 MHz.

A data sample of 2 GB, read from the random number generator with Wi-Fi enabled and the random register read at 5 MHz, has been tested using the Dieharder Random Number Testsuite (version 3.31.1). The sample passed all tests.

19. PID/MPU/MMU

19.1 Introduction

Every peripheral and memory section in the ESP32 is accessed through either an MMU (Memory Management Unit) or an MPU (Memory Protection Unit). An MPU can allow or disallow the access of an application to a memory range or peripheral, depending on what kind of permission the OS has given to that particular application. An MMU can perform the same operation, as well as a virtual-to-physical memory address translation. This can be used to map an internal or external memory range to a certain virtual memory area. These mappings can be application-specific. Therefore, each application can be adjusted and have the memory configuration that is necessary for it to run properly. To differentiate between the OS and applications, there are eight Process Identifiers (or PIDs) that each application, or OS, can run. Furthermore, each application, or OS, is equipped with their own sets of mappings and rights.

19.2 Features

- Eight processes in each of the PRO_CPU and APP_CPU
- MPU/MMU management of on-chip memories, off-chip memories, and peripherals, based on process ID
- On-chip memory management by MPU/MMU
- Off-chip memory management by MMU
- Peripheral management by MPU

19.3 Functional Description

19.3.1 PID Controller

In the ESP32, a PID controller acts as an indicator that signals the MMU/MPU the owner PID of the code that is currently running. The intention is that the OS updates the PID in the PID controller every time it switches context to another application. The PID controller can detect interrupts and automatically switch PIDs to that of the OS, if so configured.

There are two peripheral PID controllers in the system, one for each of the two CPUs in the ESP32. Having a PID controller per CPU allows running different processes on different CPUs, if so desired.

19.3.2 MPU/MMU

The MPU and MMU manage on-chip memories, off-chip memories, and peripherals. To do this they are based on the process of accessing the peripheral or memory region. More specifically, when a code tries to access a MMU/MPU-protected memory region or peripheral, the MMU or MPU will receive the PID from the PID generator that is associated with the CPU on which the process is running.

For on-chip memory and peripherals, the decisions the MMU and MPU make are only based on this PID, whereas the specific CPU the code is running on is not taken into account. Subsequently, the MMU/MPU configuration for the internal memory and peripherals allows entries only for the eight different PIDs. In contrast, the MMU moderating access to the external memory takes not only the PID into account, but also the CPU the request is coming from. This means that MMUs have configuration options for every PID when running on the APP_CPU, as well as every PID when running on the PRO_CPU. While, in practice, accesses from both CPUs will be configured to have the same result for a specific process, doing so is not a hardware requirement.

The decision an MPU can make, based on this information, is to allow or deny a process to access the memory region or peripheral. An MMU has the same function, but additionally it redirects the virtual memory access, which the process acquired, into a physical memory access that can possibly reach out an entirely different physical memory region. This way, MMU-governed memory can be remapped on a process-by-process basis.

19.3.2.1 Embedded Memory

The on-chip memory is governed by fixed-function MPUs, configurable MPUs, and MMUs:

Table 57: MPU and MMU Structure for Internal Memory

Static MPUs

ROM0, ROM1, the lower 64 KB of SRAM0, SRAM1 and the lower 72 KB of SRAM2 are governed by a static MPU. The behaviour of these MPUs are hardwired and cannot be configured by software. They moderate access to the memory region solely through the PID of the current process. When the PID of the process is 0 or 1, the memory can be read (and written when it is RAM) using the addresses specified in Table 57. When it is 2 ~ 7, the memory cannot be accessed.

RTC FAST & RTC SLOW MPU

The 8 KB RTC FAST Memory as well as the 8 KB of RTC SLOW Memory are governed by two configurable MPUs. The MPUs can be configured to allow or deny access to each individual PID, using the RTC_CNTL_RTC_PID_CONFIG_REG and DPORT_AHBLITE_MPUM_TABLE_RTC_REG registers. Setting a bit in these registers will allow the corresponding PID to read or write from the memory; clearing the bit disallows access. Access for PID 0 and 1 to RTC SLOW memory cannot be configured and is always enabled. Table 58 and 59 define the bit-to-PID mappings of the registers.

Table 58: MPU for RTC FAST Memory

Size	Boundary address		Authority PID RTC_CNTL_RTC_PID_CONFIG bit
	Low	High	
8 KB	0x3FF8_0000	0x3FF8_1FFF	0 1 2 3 4 5 6 7
8 KB	0x400C_0000	0x400C_1FFF	0 1 2 3 4 5 6 7

Table 59: MPU for RTC SLOW Memory

Size	Boundary address		PID = 0/1	Authority PID DPORT_AHBLITE_MPUM_TABLE_RTC_REG bit
	Low	High		
8 KB	0x5000_0000	0x5000_1FFF	Read/Write	2 3 4 5 6 7 0 1 2 3 4 5

Register RTC_CNTL_RTC_PID_CONFIG_REG is part of the RTC peripheral and can only be modified by processes with a PID of 0; register DPORT_AHBLITE_MPUM_TABLE_RTC_REG is a Dport register and can be changed by processes with a PID of 0 or 1.

SRAM0 and SRAM2 upper 128 KB MMUs

Both the upper 128 KB of SRAM0 and the upper 128 KB of SRAM2 are governed by an MMU. Not only can these MMUs allow or deny access to the memory they govern (just like the MPUs do), but they are also capable of translating the address a CPU reads from or writes to (which is a virtual address) to a possibly different address in memory (the physical address).

In order to accomplish this, the internal RAM MMUs divide the memory range they govern into 16 pages. The page size is configurable as 8 KB, 4 KB and 2 KB. When the page size is 8 KB, the 16 pages span the entire 128 KB memory region; when the page size is 4 KB or 2 KB, a non-MMU-covered region of 64 or 96 KB, respectively, will exist at the end of the memory space. Similar to the virtual and physical addresses, it is also possible to imagine the pages as having a virtual and physical component. The MMU can convert an address within a virtual page to an address within a physical page.

For PID 0 and 1, this mapping is 1-to-1, meaning that a read from or write to a certain virtual page will always be converted to a read from or write to the exact same physical page. This allows an operating system, running under PID 0 and/or 1, to always have access to the entire physical memory range.

For PID 2 to 7, however, every virtual page can be reconfigured, on a per-PID basis, to map to a different physical page. This way, reads and writes to an offset within a virtual page get translated into reads and writes to the

same offset within a different physical page. This is illustrated in Figure 60: the CPU (running a process with a PID between 2 to 7) tries to access memory address 0x3FFC_2345. This address is within the virtual Page 1 memory region, at offset 0x0345. The MMU is instructed that for this particular PID, it should translate an access to virtual page 1 into physical Page 2. This causes the memory access to be redirected to the same offset as the virtual memory access, yet in Page 2, which results in the effective access of physical memory address 0x3FFC_4345. The page size in this example is 8 KB.

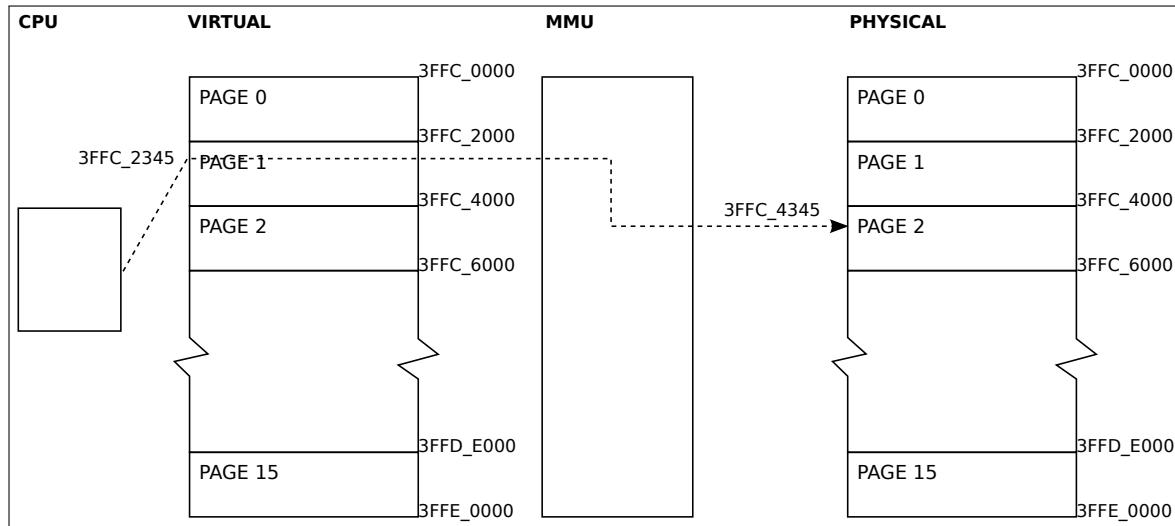

Figure 60: MMU Access Example

Table 60: Page Mode of MMU for the Remaining 128 KB of Internal SRAM0 and SRAM2

DPORT_IMMU_PAGE_MODE	DPORT_DMMU_PAGE_MODE	Page size
0	0	8 KB
1	1	4 KB
2	2	2 KB

Non-MMU Governed Memory

For the MMU-managed region of SRAM0 and SRAM2, the page size is configurable as 8 KB, 4 KB and 2 KB. The configuration is done by setting the DPORT_IMMU_PAGE_MODE (for SRAM0) and DPORT_DMMU_PAGE_MODE (for SRAM2) bits in registers DPORT_IMMU_PAGE_MODE_REG and DPORT_DMMU_PAGE_MODE_REG, as detailed in Table 60. Because the number of pages for either region is fixed at 16, the total amount of memory covered by these pages is 128 KB when 8 KB pages are selected, 64 KB when 4 KB pages are selected, and 32 KB when 2 KB pages are selected. This implies that for 8 KB pages, the entire MMU-managed range is used, but for the other page sizes there will be a part of the 128 KB memory that will not be governed by the MMU settings. Concretely, for a page size of 4 KB, these regions are 0x4009_0000 to 0x4009_FFFF and 0x3FFD_0000 to 0x3FFD_FFFF; for a page size of 2 KB, the regions are 0x4008_8000 to 0x4009_FFFF and 0x3FFC_8000 to 0x3FFD_FFFF. These ranges are readable and writable by processes with a PID of 0 or 1; processes with other PIDs cannot access this memory.

The layout of the pages in memory space is linear, namely, an SRAM0 MMU page n covers address space $0x40080000 + (\text{pagesize} * n)$ to $0x40080000 + (\text{pagesize} * (n + 1) - 1)$; similarly, an SRAM2 MMU page n covers $0x3FFC0000 + (\text{pagesize} * n)$ to $0x3FFC0000 + (\text{pagesize} * (n + 1) - 1)$. Tables 61 and 62 show the resulting addresses in full.

MMU Mapping

For each of the SRAM0 and SRAM2 MMUs, access rights and virtual to physical page mapping are done by a set of 16 registers. In contrast to most of the other MMUs, each register controls a physical page, not a virtual one. These registers control which of the PIDs have access to the physical memory, as well as which virtual page maps to this physical page. The bits in the register are described in Table 63. Keep in mind that these registers only govern accesses from processes with PID 2 to 7; PID 0 and 1 always have full read and write access to all pages and no virtual-to-physical mapping is done. In other words, if a process with a PID of 0 or 1 accesses virtual page x , the access will always go to physical page x , regardless of these register settings. These registers, as well as the page size selection registers DPOR_T_IMMU_PAGE_MODE_REG and DPOR_T_DMMU_PAGE_MODE_REG, are only writable from a process with PID 0 or 1.

Differences Between SRAM0 and SRAM2 MMU

The memory governed by the SRAM0 MMU is accessed through the processors I-bus, while the processor accesses the memory governed by the SRAM2 MMU through the D-bus. Thus, the normal envisioned use is for the code to be stored in the SRAM0 MMU pages and data in the MMU pages of SRAM2. In general, applications running under a PID of 2 to 7 are not expected to modify their own code, because for these PIDs access to the MMU pages of SRAM0 is read-only. These applications must, however, be able to modify their data section, so that they are allowed to read as well as write MMU pages located in SRAM2. As stated before, processes running under PID 0 or 1 always have full read-and-write access to both memory ranges.

DMA MPU

Applications may want to configure the DMA to send data straight from or to the peripherals they can control. With access to DMA, a malicious process may also be able to copy data from or to a region it cannot normally

access. In order to be secure against that scenario, there is a DMA MPU which can be used to disallow DMA transfers from memory regions with sensitive data in them.

For each 8 KB region in the SRAM1 and SRAM2 regions, there is a bit in the DPORT_AHB_MPUMPU_TABLE_0_REG registers which tells the MPU to either allow or disallow DMA access to this region. The DMA MPU uses only these bits to decide if a DMA transfer can be started; the PID of the process is not a factor. This means that when the OS wants to restrict its processes in a heterogenous fashion, it will need to re-load these registers with the values applicable to the process to be run on every context switch.

The register bits that govern access to the 8 KB regions are detailed in Table 64. When a register bit is set, DMA can read/write the corresponding 8 KB memory range. When the bit is cleared, access to that memory range is denied.

Registers DPROT_AHB_MPUMPU_TABLE_0_REG DPROT_AHB_MPUMPU_TABLE_1_REG are located in the DPort address space. Only processes with a PID of 0 or 1 can modify these two registers.

19.3.2.2 External Memory

Accesses to the external flash and external SPI RAM are done through a cache and are also handled by an MMU. This Cache MMU can apply different mappings, depending on the PID of the process as well as the CPU the process is running on. The MMU does this in a way that is similar to the internal memory MMU, that is, for every page of virtual memory, it has a register detailing which physical page this virtual page should map to. There are differences between the MMUs governing the internal memory and the Cache MMU, though. First of all, the Cache MMU has a fixed page size (which is 64 KB for external flash and 32 KB for external RAM) and secondly, instead of specifying access rights in the MMU entries, the Cache MMU has explicit mapping tables for each PID and processor core. The MMU mapping configuration registers will be referred to as 'entries' in the rest of this chapter. These registers are only accessible from processes with a PID of 0 or 1; processes with a PID of 2 to 7 will have to delegate to one of the above-mentioned processes to change their MMU settings.

The MMU entries, as stated before, are used for mapping a virtual memory page access to a physical memory page access. The MMU controls five regions of virtual address space, detailed in Table 65. $VAddr_1$ to $VAddr_4$ are used for accessing external flash, whereas $VAddr_{RAM}$ is used for accessing external RAM. Note that $VAddr_4$ is a subset of $VAddr_0$.

Table 65: Virtual Address for External Memory

Name	Size	Boundary address		Page quantity
		Low	High	
$VAddr_0$	4 MB	0x3F40_0000	0x3F7F_FFFF	64
$VAddr_1$	4 MB	0x4000_0000	0x403F_FFFF	64*
$VAddr_2$	4 MB	0x4040_0000	0x407F_FFFF	64
$VAddr_3$	4 MB	0x4080_0000	0x40BF_FFFF	64
$VAddr_4$	1 MB	0x3F40_0000	0x3F4F_FFFF	16
$VAddr_{RAM}$	4 MB	0x3F80_0000	0x3FBF_FFFF	128

* The configuration entries for address range 0x4000_0000 ~ 0x403F_FFFF are implemented and documented as if it were a full 4 MB address range, but it is not accessible as such. Instead, the address range 0x4000_0000 ~ 0x400C_1FFF accesses on-chip memory. This means that some of the configuration entries for $VAddr_1$ will not be used.

External Flash

For flash, the relationships among entry numbers, virtual memory ranges, and PIDs are detailed in Tables 66 and 67, which for every memory region and PID combination specify the first MMU entry governing the mapping. This number refers to the MMU entry governing the very first page; the entire region is described by the amount of pages specified in the 'count' column.

These two tables are essentially the same, with the sole difference being that the APP_CPU entry numbers are 2048 higher than the corresponding PRO_CPU numbers. Note that memory regions $VAddr_0$ and $VAddr_1$ are only accessible using PID 0 and 1, while $VAddr_4$ can only be accessed by PID 2 ~ 7.

Table 66: MMU Entry Numbers for PRO_CPU

VAddr	Count	First MMU entry for PID						
		0/1	2	3	4	5	6	7
$VAddr_0$	64	0	-	-	-	-	-	-
$VAddr_1$	64	64	-	-	-	-	-	-
$VAddr_2$	64	128	256	384	512	640	768	896
$VAddr_3$	64	192	320	448	576	704	832	960
$VAddr_4$	16	-	1056	1072	1088	1104	1120	1136

Table 67: MMU Entry Numbers for APP_CPU

$VAddr_4$	16	-	3104	3120	3136	3152	3168	3184

As these tables show, virtual address $VAddr_1$ can only be used by processes with a PID of 0 or 1. There is a

special mode to allow processes with a PID of 2 to 7 to read the External Flash via address $VAddr_1$. When the DPORTE_PRO_SINGLE_IRAM_ENA bit of register DPORTE_PRO_CACHE_CTRL_REG is 1, the MMU enters this special mode for PRO_CPU memory accesses. Similarly, when the DPORTE_APP_SINGLE_IRAM_ENA bit of register DPORTE_APP_CACHE_CTRL_REG is 1, the APP_CPU accesses memory using this special mode. In this mode, the process and virtual address page supported by each configuration entry of MMU are different. For details please see Table 68 and 69. As shown in these tables, in this special mode $VAddr_2$ and $VAddr_3$ cannot be used to access External Flash.

Table 68: MMU Entry Numbers for PRO_CPU (Special Mode)

VAddr	Count	First MMU entry for PID						
		0/1	2	3	4	5	6	7
$VAddr_0$	64	0	-	-	-	-	-	-
$VAddr_1$	64	64	256	384	512	640	768	896

$VAddr_4$	16	-	3104	3120	3136	3152	3168	3184

Every configuration entry of MMU maps a virtual address page of a CPU process to a physical address page. An entry is 32 bits wide. Of these, bits 0~7 indicate the physical page the virtual page is mapped to. Bit 8 should be cleared to indicate that the MMU entry is valid; entries with this bit set will not map any physical address to the virtual address. Bits 10 to 32 are unused and should be written as zero. Because there are eight address bits in an MMU entry, and the page size for external flash is 64 KB, a maximum of $256 * 64 \text{ KB} = 16 \text{ MB}$ of external flash is supported.

Examples

Example 1. A PRO_CPU process, with a PID of 1, needs to read external flash address 0x07_2375 via virtual address 0x3F70_2375. The MMU is not in the special mode.

- According to Table 65, virtual address 0x3F70_2375 resides in the 0x30'th page of $VAddr_0$.
- According to Table 66, the MMU entry for $VAddr_0$ for PID 0/1 for the PRO_CPU starts at 0.
- The modified MMU entry is $0 + 0x30 = 0x30$.
- Address 0x07_2375 resides in the 7'th 64 KB-sized page.
- MMU entry 0x30 needs to be set to 7 and marked as valid by setting the 8'th bit to 0. Thus, 0x007 is written to MMU entry 0x30.

Example 2. An APP_CPU process, with a PID of 4, needs to read external flash address 0x44_048C via virtual address 0x4044_048C. The MMU is not in special mode.

- According to Table 65, virtual address 0x4044_048C resides in the 0x4'th page of $V\text{Addr}_2$.
- According to Table 67, the MMU entry for $V\text{Addr}_2$ for PID 4 for the APP_CPU starts at 2560.
- The modified MMU entry is $2560 + 0x4 = 2564$.
- Address 0x44_048C resides in the 0x44'th 64 KB-sized page.
- MMU entry 2564 needs to be set to 0x44 and marked as valid by setting the 8'th bit to 0. Thus, 0x044 is written to MMU entry 2564.

External RAM

Processes running on PRO_CPU and APP_CPU can read and write External SRAM via the Cache at virtual address range $V\text{Addr}_{RAM}$, which is $0x3F80_0000 \sim 0x3FBF_FFFF$. As with the flash MMU, the address space and the physical memory are divided into pages. For the External RAM MMU, the page size is 32 KB and the MMU is able to map 256 physical pages into the virtual address space, allowing for $32\text{ KB} * 256 = 8\text{ MB}$ of physical external RAM to be mapped.

The mapping of virtual pages into this memory range depends on the mode this MMU is in: Low-High mode, Even-Odd mode, or Normal mode. In all cases, the DPORT_PRO_DRAM_HL bit and DPORT_PRO_DRAM_SPLIT bit in register DPORT_PRO_CACHE_CTRL_REG, the DPORT_APP_DRAM_HL bit and DPORT_APP_DRAM_SPLIT bit in register DPORT_APP_CACHE_CTRL_REG determine the virtual address mode for External SRAM. For details, please see Table 70. If a different mapping for the PRO_CPU and APP_CPU is required, the Normal Mode should be selected, as it is the only mode that can provide this. If it is allowable for the PRO_CPU and the APP_CPU to share the same mapping, using either High-Low or Even-Odd mode can give a speed gain when both CPUs access memory frequently.

In case the APP_CPU cache is disabled, which renders the region of $0x4007_8000$ to $0x4007_FFFF$ usable as normal internal RAM, the usability of the various cache modes changes. Normal mode will allow PRO_CPU access to external RAM to keep functioning, but the APP_CPU will be unable to access the external RAM. High-Low mode allows both CPUs to use external RAM, but only for the 2 MB virtual memory addresses from $0x3F80_0000$ to $0x3F9F_FFFF$. It is not advised to use Even-Odd mode with the APP_CPU cache region disabled.

Table 70: Virtual Address Mode for External SRAM

Mode	DPORT_PRO_DRAM_HL DPORT_APP_DRAM_HL	DPORT_PRO_DRAM_SPLIT DPORT_APP_DRAM_SPLIT
Low-High	1	0
Even-Odd	0	1
Normal	0	0

In normal mode, the virtual-to-physical page mapping can be different for both CPUs. Page mappings for PRO_CPU are set using the MMU entries for ${}^L V\text{Addr}_{RAM}$, and page mappings for the APP_CPU can be configured using the MMU entries for ${}^R V\text{Addr}_{RAM}$. In this mode, all 128 pages of both ${}^L V\text{Addr}$ and ${}^R V\text{Addr}$ are fully used, allowing a maximum of 8 MB of memory to be mapped; 4 MB into PRO_CPU address space and a possibly different 4 MB into the APP_CPU address space, as can be seen in Table 71.

Table 71: Virtual Address for External SRAM (Normal Mode)

Virtual address	Size	PRO_CPU address	
		Low	High
${}^L V Addr_{RAM}$	4 MB	0x3F80_0000	0x3FBF_FFFF
Virtual address	Size	APP_CPU address	
${}^R V Addr_{RAM}$	4 MB	0x3F80_0000	0x3FBF_FFFF

In Low-High mode, both the PRO_CPU and the APP_CPU use the same mapping entries. In this mode ${}^L V Addr_{RAM}$ is used for the lower 2 MB of the virtual address space, while ${}^R V Addr_{RAM}$ is used for the upper 2 MB. This also means that the upper 64 MMU entries for ${}^L V Addr_{RAM}$, as well as the lower 64 entries for ${}^R V Addr_{RAM}$, are unused. Table 72 details these address ranges.

Table 72: Virtual Address for External SRAM (Low-High Mode)

Virtual address	Size	PRO_CPU/APP_CPU address	
		Low	High
${}^L V Addr_{RAM}$	2 MB	0x3F80_0000	0x3F9F_FFFF
${}^R V Addr_{RAM}$	2 MB	0x3FA0_0000	0x3FBF_FFFF

In Even-Odd memory, the VRAM is split into 32-byte chunks. The even chunks are resolved through the MMU entries for ${}^L V Addr_{RAM}$, the odd chunks through the entries for ${}^R V Addr_{RAM}$. Generally, the MMU entries for ${}^L V Addr_{RAM}$ and ${}^R V Addr_{RAM}$ are set to the same values, so that the virtual pages map to a contiguous region of physical memory. Table 73 details this mode.

Table 73: Virtual Address for External SRAM (Even-Odd Mode)

Virtual address	Size	PRO_CPU/APP_CPU address	
		Low	High
${}^L V Addr_{RAM}$	32 Bytes	0x3F80_0000	0x3F80_001F
${}^R V Addr_{RAM}$	32 Bytes	0x3F80_0020	0x3F80_003F
${}^L V Addr_{RAM}$	32 Bytes	0x3F80_0040	0x3F80_005F
${}^R V Addr_{RAM}$	32 Bytes	0x3F80_0060	0x3F80_007F
...			
${}^L V Addr_{RAM}$	32 Bytes	0x3FBF_FFC0	0x3FBF_FFDF
${}^R V Addr_{RAM}$	32 Bytes	0x3FBF_FFE0	0x3FBF_FFFF

The bit configuration of the External RAM MMU entries is the same as for the flash memory: the entries are 32-bit registers, with the lower nine bits being used. Bits 0~7 contain the physical page the entry should map its associate virtual page address to, while bit 8 is cleared when the entry is valid and set when it is not. Table 74 details the first MMU entry number for ${}^L V Addr_{RAM}$ and ${}^R V Addr_{RAM}$ for all PIDs.

Table 74: MMU Entry Numbers for External RAM

VAddr	Count	First MMU entry for PID						
		0/1	2	3	4	5	6	7
${}^L V Addr_{RAM}$	128	1152	1280	1408	1536	1664	1792	1920
${}^R V Addr_{RAM}$	128	3200	3328	3456	3584	3712	3840	3968

Examples

Example 1. A PRO_CPU process, with a PID of 7, needs to read or write external RAM address 0x7F_A375 via virtual address 0x3FA7_2375. The MMU is in Low-High mode.

- According to Table 65, virtual address 0x3FA7_2375 resides in the 0x4E'th 32-KB-page of $V Addr_{RAM}$.
- According to Table 72, virtual address 0x3FA7_2375 is governed by ${}^R V Addr_{RAM}$.
- According to Table 74, the MMU entry for ${}^R V Addr_{RAM}$ for PID 7 for the PRO_CPU starts at 3968.
- The modified MMU entry is $3968 + 0x4E = 4046$.
- Address 0x7F_A375 resides in the 255'th 32 KB-sized page.
- MMU entry 4046 needs to be set to 255 and marked as valid by clearing the 8'th bit. Thus, 0x0FF is written to MMU entry 4046.

Example 2. An APP_CPU process, with a PID of 5, needs to read or write external RAM address 0x55_5805 up to 0x55_5823 starting at virtual address 0x3F85_5805. The MMU is in Even-Odd mode.

- According to Table 65, virtual address 0x3F85_5805 resides in the 0x0A'th 32-KB-page of $V Addr_{RAM}$.
- According to Table 73, the range to be read/written spans both a 32-byte region in ${}^R V Addr_{RAM}$ and ${}^L V Addr_{RAM}$.
- According to Table 74, the MMU entry for ${}^L V Addr_{RAM}$ for PID 5 starts at 1664.
- According to Table 74, the MMU entry for ${}^R V Addr_{RAM}$ for PID 5 starts at 3712.
- The modified MMU entries are $1664 + 0x0A = 1674$ and $3712 + 0x0A = 3722$.
- The addresses 0x55_5805 to 0x55_5823 reside in the 0xAA'th 32 KB-sized page.
- MMU entries 1674 and 3722 need to be set to 0xAA and marked as valid by setting the 8'th bit to 0. Thus, 0x0AA is written to MMU entries 1674 and 3722. This mapping applies to both the PRO_CPU and the APP_CPU.

Example 3. A PRO_CPU process, with a PID of 1, and an APP_CPU process whose PID is also 1, need to read or write external RAM using virtual address 0x3F80_0876. The PRO_CPU needs this region to access physical address 0x10_0876, while the APP_CPU wants to access physical address 0x20_0876 through this virtual address. The MMU is in Normal mode.

- According to Table 65, virtual address 0x3F80_0876 resides in the 0'th 32-KB-page of $V Addr_{RAM}$.
- According to Table 74, the MMU entry for PID 1 for the PRO_CPU starts at 1152.
- According to Table 74, the MMU entry for PID 1 for the APP_CPU starts at 3200.
- The MMU entries that are modified are $1152 + 0 = 1152$ for the PRO_CPU and $3200 + 0 = 3200$ for the APP_CPU.
- Address 0x10_0876 resides in the 0x20'th 32 KB-sized page.
- Address 0x20_0876 resides in the 0x40'th 32 KB-sized page.
- For the PRO_CPU, MMU entry 1152 needs to be set to 0x20 and marked as valid by clearing the 8'th bit. Thus, 0x020 is written to MMU entry 1152.

- For the APP_CPU, MMU entry 3200 needs to be set to 0x40 and marked as valid by clearing the 8'th bit. Thus, 0x040 is written to MMU entry 3200.
- Now, the PRO_CPU and the APP_CPU can access different physical memory regions through the same virtual address.

19.3.2.3 Peripheral

The Peripheral MPU manages the 41 peripheral modules. This MMU can be configured per peripheral to only allow access from a process with a certain PID. The registers to configure this are detailed in Table 75.

Each bit of register DPORT_AHBLITE_MPUMPUTABLE_X_REG determines whether each process can access the peripherals managed by the register. For details please see Table 76. When a bit of register DPORT_AHBLITE_MPUMPUTABLE_X_REG is 1, it means that a process with the corresponding PID can access the corresponding peripheral of the register. Otherwise, the process cannot access the corresponding peripheral.
